Automorphic forms for unitary groups and
Galois representations

Three lectures at the Clay Mathematical Institute Summer School,
Honolulu, Hawaii, 2009

These modest notes are a shortened version of four lectures given at Hawaii for
the CMI summer school on Galois representations. They contain a short survey
of the theory of unitary groups over a number field and, in the definite cases, of
their automorphic forms, and of the Galois representations that we can attach to
those. Very few proofs are given. I hope however that these notes may serve as a
quick introduction, and as a very partial summary, of this recent and fundamental
achievement that we are now able to construct Galois representations for all auto-
morphic representations of definite unitary groups, and to describe them precisely
enough at every local place.

The lectures I gave at Hawaii were more ambitious. The presentation of the
results on automorphic forms for unitary groups and Galois representations were
just an introduction, and I went on to explain the eigenvarieties of the definite
unitary groups, and how one can use them to prove, using the generalizations of
Ribet’s lemma explained in my previous lectures [B3], some cases of the conjecture
of Bloch and Kato [B2]. By lack of time my exposition became more and more
sketchy, and I do not think that notes following that exposition would be useful
to anyone, and expending them to the size they deserve (at least 100 pages) has
proved beyond my energy. Therefore, I redirect the reader to the very nice paper
[Buz] for an introduction to the theory of eigenvarieties, to [Ch1], [E1], or [BC2,
chapter VII] for eigenvarieties of definite unitary groups, and to [BC2, chapter VIII
and IX] for the applications to the Bloch-Kato conjecture I have tried to explain
at Hawaii.

Prerequisites: The prerequisites for these lectures are:

(i) Notions on algebraic groups.
(ii) If possible, classical modular forms, and their adelic interpretation.

Notations: During most of the lecture, $F$ will be a number field. The ring of
adèles will be denoted by $\mathbb{A}_F$ or simply $\mathbb{A}$. It is a product $\mathbb{A}_F = \mathbb{A}_{F,f} \times \mathbb{A}_{F,\infty}$ of
finite adèles $\mathbb{A}_{F,f} = \mathbb{A}_f$ and infinite adèles $\mathbb{A}_{F,\infty} = \mathbb{A}_\infty = F \otimes \mathbb{Q} \mathbb{R}$. When $g$ is an
adèle (or an idèle, or an adèle-valued point of a group scheme over $F$) we denote by
$g_f$ and $g_\infty$ its finite and infinite components. We often identify $g_f$ with the adèle (or idèle, etc.) which has the same finite components and 0 (or 1) at all infinite component, and similarly for $g_\infty$ so that $g = g_f + g_\infty$ (or $g = g_f g_\infty$).

We shall denote by $\overline{\mathbb{Q}}$ the set of complex numbers that are algebraic over $\mathbb{Q}$. So $\overline{\mathbb{Q}}$ is supposed to be embedded in $\mathbb{C}$.

These notes are about automorphic forms and representations for unitary groups, and their attached Galois representations. The very existence of those attached representations is a recent progress that constitutes one of the most important achievement in the still largely open Langlands’ program. It has been the result of a huge collective work of many mathematicians over more than thirty years (realizing an initial sketch, incredibly accurate in retrospect, of Langlands in the seventies). It is absolutely out of question to give or even tho sketch the proof of this existence in this paper.

The aim of this lecture is only to provide a short and intuitive introduction to automorphic forms and representations for unitary groups, and to state the existence and main properties of their attached Galois representations. Even simply giving a proper and workable definition of automorphic representations for a general unitary group is a task that cannot be properly done in less than 100 pages.
There are many technical difficulties (especially at the archimedean places), which, through important, are not essential to the intuitive understanding of the notions. To avoid most of those difficulties, I will only consider a special case, namely unitary groups that are definite, that is compact at all archimedean places. While there are many arithmetical applications for which this special case may be sufficient, considering the general case is necessary in many other (including some that might be explained by Chris using Eisenstein series, which only exists for non-definite unitary groups) and moreover, the construction of Galois representations requires to consider non-definite places.

A natural question is: why unitary groups? The short answer is simply: because they are (with a few sporadic other cases, most notably Sp\(_4\)) the only algebraic group for which we know, at this point, how to attach Galois representation to most automorphic representations. We should be able to do the same to many other automorphic representations (e.g. all algebraic automorphic representations for GL\(_n\)) but it seems that some very difficult new ideas are missing in order to do that.

1. Unitary groups

1.1. Generalities. Let \( k \) be a field of characteristic 0 (for simplicity), and \( E \) be an étale algebra of dimension 2 over \( k \) (that is to say, \( E \) is either \( k \times k \) or it is a field of degree 2 over \( E \)). The algebra \( E \) has only one non-trivial \( k \)-automorphism that we shall denote by \( c \). Let \( V \) be a free \( E \)-module of rank \( n \), and \( q : V \times V \to E \) be a non-degenerate \( c \)-Hermitian form. (That is to say, \( q(x, y) \) is \( E \)-linear in \( x \) and \( c \)-semi-linear in \( y \), we have \( q(x, y) = c(q(y, x)) \) for all \( x, y \in V \), and \( q(x, y) = 0 \ \forall y \in V \) implies \( x = 0 \).)

To these data \((k, E, V, q)\) we can attach an algebraic group over \( k \).

**Definition 1.1.** The unitary group \( G \) attached to \((k, E, V, q)\) is the algebraic group whose functor of points is

\[
G(R) = \{ g \in \text{GL}_{E \otimes_k R}(V \otimes_k R), \ q(gx, gy) = q(x, y) \ \forall x, y \in V \otimes_k R \}.
\]

for every \( k \)-algebra \( R \). In the case where \( E \) is a field (rather than \( k \times k \)) we shall say that \( G \) is a true unitary group.

Intuitively, this is not very complicated. The \( k \)-points of the unitary group are the set of \( E \)-linear automorphisms of \( V \) that preserve the Hermitian form \( q \). Similarly for \( R \)-points.

**Exercise 1.1.** This definition implicitly assumes that the functor \( R \mapsto G(R) \) is representable by a scheme over \( k \). Prove it.

**Exercise 1.2.** Assume \((k, E)\) are fixed. We say that \((V, q)\) and \((V', q')\) are equivalent if there is an \( E \)-linear isomorphism \( f : V \to V' \) such that \( q'(f(x), f(y)) = q(x, y) \) for all \( x, y \in V \). Prove it.
$q(x, y)$ for all $x, y \in V$. We say that $(V, q)$ and $(V, q')$ are quasi-equivalent if $(V, q)$ is equivalent to $(V', \alpha q')$ for some $\alpha \in E^*$. Show that if $(V, q)$ and $(V', q')$ are quasi-equivalent, then the unitary groups attached to $(k, E, V, q)$ and $(k, E', V', q')$ are $k$-isomorphic.

**Proposition 1.1.** If $E$ is $k \times k$, then the unitary group $G$ is isomorphic to $GL_n$. More precisely, one we have chosen one of the two $k$-morphisms $E \to k$, there is is an isomorphism of $k$-algebraic groups $G \to GL_n$ which is canonical up to inner automorphism of $GL_n$. Changing the morphism $E \mapsto k$ amounts to changing the above isomorphism by an outer automorphism of $GL_n$.

**Proof.** Let $p : E \to k$ be a $k$-morphism. The choice of $p$ makes the isomorphism $E = k \times k$ (as $k$-algebra canonical, by saying that $p$ is the first projection on $k \times k$). Let $V_0 = V \otimes_{E, p} k$. We construct an morphism of functors $G(R) \to GL_R(V_0 \otimes_k R)$ by sending $g \in G(R)$ (an $E$-automorphism on $V \otimes_E R$) to its action on $V \otimes_E R \otimes_E k = V_0 \otimes_k R$. We leave to the reader to check that is an isomorphism. \hfill \Box

In other words, if a unitary group is not a true unitary group, it is isomorphic to $GL_n$.

Now, let $k'$ be any extension of $k$. We can consider $E' = E \otimes_k k'$ which is still an etale algebra over $k'$ (but not that if $E$ was a field, this may fail for $E'$, hence the interest of the generality adopted), $V' = V \otimes_E E'$ which is still free of rank $n$ over $E$, and $q'$ the natural extension of $q$ to $V'$. To the data $(k', E', V', q')$ one can attach an unitary group $G'$ over $k'$. It is clear from the definition that $G'$ is $G \times_k k'$.

In particular, if $k' = E, G \times_k E$ is the unitary group attached to $(E, E \otimes_k E, V', q')$ for some $V'$ and $q'$. But since $E \otimes_k E$ is isomorphic to $E \times E$, we see by Prop 1.1 that $G \times_k E$ is isomorphic to $GL_n$. So unitary group are always forms of $GL_n$.

**Exercise 1.3.** 1.– Let $H$ be a $k$-algebraic subgroup of a true unitary group $G$ (attached to $(k, E, V, q)$ as above). Assume that $H$ is a split torus, i.e. isomorphic to $GL^d_m$ for some $d$. Show that there exists $d$ linearly independent vector $e_1, \ldots, e_d$ in $V$ such that $q(e_i, e_j) = 0$ for all $1 \leq i, j \leq d$. Deduce that $2d \leq \dim V$

2.– Deduce that a true unitary group over $k$ is not isomorphic to $GL_n$.

3.– Deduce that if the unitary group attached to $(k, E, V, q)$ and to $(k, E, V', q')$ then $E \simeq E'$ as $k$-algebras.

**Exercise 1.4. (easy)** This exercise recalls basics of the theory of hermitian form. Let $(k, E, V, q)$ be as usual, with $E$ a field. We say that a vector $v \in V$ is isotropic and we say that a subspace $H$ of $V$ is an hyperbolic plane if it has a basis $v, w$ with $q(v, v) = q(w, w) = 0$ and $q(v, w) = q(w, v) = 1$.

1.– Let $v$ be a non-zero isotropic vector in $V$. Show that $v$ belongs to an isotropic subspace of $v$. 
If $H$ is a subspace of $V$, we call $H^\perp$ the set of $w \in V$ such that $q(v, w) = 0$ for all $v \in H$.

2.– Show that $H^\perp$ is a subspace of $V$ of dimension $\dim V - \dim H$. Show that $(H^\perp)^\perp = H$. Show that if $H$ is a line generated by a non-isotropic vector, or is an hyperbolic plane, then $V = H \oplus H^\perp$.

**Remark 1.1.** The definition we have given of unitary group is quite intuitive. Unfortunately this not the most general one, nor the most natural from the point of view of the theory of descent. The general definition may be a little bit frightening at first glance, which is why I preferred to use the above ”naive” definition. In order to motivate the general definition, let us first reformulate the naive definition. If $(k, E, V, q)$ is as above, then for any endomorphism $u \in \operatorname{End}_E(V)$ there is a unique endomorphism $u^* \in \operatorname{End}_E(V)$ such that

$$q(u(x), y) = q(x, u^*(y)) \text{ for all } x, y \in V.$$ 

The application $u \mapsto u^*$ is an anti-involution of the algebra $\operatorname{End}_E(V)$ which induces $c$ on the scalars $E \subset \operatorname{End}_E(V)$. We see easily that our definition of the unitary group $G$ is equivalent to

$$G(R) = \{g \in (\operatorname{End}_E(V) \otimes_k R)^*, g^* g = \text{Id} \}.$$ 

Now the algebra $\operatorname{End}_E(V)$ is a matrix algebra isomorphic to $M_n(E)$ if $\dim V = n$. We know that an algebra whose base change is a matrix algebra may not be a matrix algebra, but is a central simple algebra. So we are led to the following definition:

Let $\Delta$ be a central simple algebra over $E$, and $u \mapsto u^*$ an anti-involution of the second kind of $\Delta$ (that is an additive anti-involution that induces $c$ on the scalars $E \subset \Delta$). Then the unitary group attached to $(k, E, \Delta, *)$ is the group $G$ such that

$$G(R) = \{g \in (\Delta \otimes_k R)^*, g^* g = \text{Id} \}.$$ 

We thus have a more general notion of unitary group, which reduces to the naive one when $\Delta$ is a matrix algebra (exercise). However for simplicity, we will stick to the naive definition.

1.2. **Unitary groups on real and $p$-adic fields.** First assume that $k = \mathbb{R}$, $E = \mathbb{C}$, $V$ a space of dimension $n$ over $E = \mathbb{C}$.

**Exercise 1.5.** Show that any non-degenerate hermitian form on $V$ is equivalent to the form

$$q_p((x_1, \ldots, x_n), (y_1, \ldots, y_n)) = x_1 c(y_1) + \cdots + x_p c(y_p) - x_{p+1} c(y_{p+1}) - \cdots - x_n c(y_n)$$

on $\mathbb{C}^n$, for some integer $p$ such that $0 \leq p \leq n$. Show that $q_p$ is equivalent (resp. quasi-equivalent) to $q_{p'}$ if and only if $p = p' \ (p = p' \text{ or } p = n - p')$. 
As a consequence, any true unitary group on $\mathbb{R}$ is equivalent to the unitary group attached to the form $q_p$, which is denoted by $U(p, n - p)$.

**Exercise 1.6.** Let $p, q$ be two non-negative integer, with $p + q > 0$. Show that $U(p, q) \simeq U(p', q')$ if and only if $\{p, q\} = \{p', q'\}$. Show that $U(p, q)(\mathbb{R})$ is a compact group if and only if $pq = 0$.

Now we assume that $k$ is a finite extension of $\mathbb{Q}_p$, and $E$ a quadratic extension of $\mathbb{Q}_p$, $V$ a space of dimension $n$.

The following exercise will classify the non-degenerate hermitian forms $q$ over $V$. For this we need to recall some (probably well-known) notions. A vector $v$ is isotropic for $q$ if $q(v, v) = 0$.

**Exercise 1.7.** Let $q$ be any non-degenerate hermitian form on $V$. Set $n = \dim V$.

1. Recall from Serre that any quadratic form over a space of dimension at least 5 has a non-zero isotropic vector. Deduce that if $\dim V \geq 3$, then $q$ has a non-zero isotropic vector.

2. Assume that $V$ has dimension 1. Show that the values of $q(v, v)$ for $v \in V$ form a class in $k^*/N_{E/k}(E^*)$. Deduce that there are 2 equivalence classes of hermitian forms in dimension 1, that are quasi-equivalent.

3. Assume that $n$ is odd, $n = 2m + 1$. Show that $V$ has a decomposition $V = H_1 \oplus \cdots \oplus H_m \oplus L$, where the $H_i$ are hyperbolic plane and $L$ is a line generated by an isotropic vector. Observe that the values $q(v, v)$ for $v \in L$ are in the same class on $k^*/N_{E/k}(E^*)$ that the discriminant of $q$. Deduce that there are exactly two equivalence classes of non-degenerate $c$-hermitian form over $V$, and that those two classes are quasi-equivalent.

3. Assume that $n$ is even, $n = 2m$. Show that $V$ has either a decomposition $V = H_1 \oplus \cdots \oplus H_m$, or a decomposition $V = H^1 \oplus \cdots \oplus H_{m-1} \oplus L \oplus L'$ where the two Hermitian lines $V$ and $V'$ are not equivalent. Deduce that there are exactly two equivalence class of $c$-Hermitian form on $V$, and that they are not quasi-equivalent.

Since quasi-equivalent hermitian forms define isomorphic unitary groups, we see that there is one class of true unitary groups in the odd-dimensional case, and at most 2 in the even-dimensional case.

**Exercise 1.8. (difficult)** 1. Assume $\dim V$ is even. Show that the two unitary groups attached to the two classes of hermitian form defined in the above exercise are not isotropic, by showing that only one of them is quasi-split (that is, has a Borel subgroup defined over $k$).

2. Assume that $\dim V$ is odd. Show that the unitary group attached to $(V, q)$ is quasi-split.
1.3. Unitary groups over totally real number fields. Let $F$ be a totally real finite extension of $\mathbb{Q}$, and $E$ be a quadratic extension of $E$ that is totally imaginary. In other words, $E$ is a CM field. Let $c$ be the non-trivial automorphism of $E$ over $F$. Let $V$ be an $E$-vector space of dimension $n$ and $q$ be a non-degenerate $c$-hermitian form on $V$. To $(F, E, V, q)$ one can attach a (true) unitary group $G$ over $F$.

To get a better understanding of $G$ we analyze the groups $G_v := G \times_F F_v$ for all places $v$ of $F$.

If $v$ is archimedean, then by assumption $v$ is real, that is $F_v = \mathbb{R}$, and $E_v = \mathbb{C}$, while $c$ induces the complex conjugation on $\mathbb{C}$. The group $G_v$ is therefore $\mathbb{R}$-isomorphic to a group $U(p_v, n - p_v)$ for some $0 \leq p_v \leq n$ as in Exercise 1.6.

**Definition 1.2.** We shall say that $G$ is **definite** if $G_v$ is compact (that is $p_v = 0$ or $p_v = n$) for all real places $v$ of $F$.

If $v$ is **finite and split** in $E$, then $E \otimes_F F_v$ is not a field, but is isomorphic to $F_v \times F_v$. Therefore, the group $G_v$ which is the unitary group attached to $(F_v, E \otimes_F F_v, \ldots, \ldots)$ is by Prop 1.1 isomorphic to $GL_n$ over $F_v$. The choice of one of the two $F_v$-morphisms $E \otimes_F F_v$ to $F_V$, that is of one of the two places of $E$ above $v$ makes this isomorphism canonical, up to conjugation.

If $v$ is **finite and either inert or ramified** in $E$, then $E_v$ is a quadratic extension of $F_v$, so $G_v$ is a true unitary groups of $v$. Therefore, there is only one possibility for $G_v$ if $\dim V$ is odd, and two if $v$ is even. In the latter case, $G_v$ can be quasi-split, or not. It is easy to see that it is quasi-split for almost all $v$.

The point to remember (for beginners) is that even a true unitary group over $F$ becomes $GL_n$ at basically one place of $F$ over two: the places that are split in $E$. This will be very helpful later.

Slightly more advanced is the following classification theorem:

**Theorem 1.1.** 1.– If $G$ and $G'$ are two unitary groups such that $G_v \simeq G'_v$ for all place $v$ of $F$, then $G \simeq G'$.

2.– Let $(G_v)_v$ be a family of unitary groups over $F_v$, attached to the extension $E \times F_v/F_v$. We assume that $G_v$ is quasi-split for almost all $v$. Then if $\dim V$ is odd, there is a true unitary group $G$ attached to $E/F$ such that for every place $v$ of $F$, $G_v$ is the unitary group from the family. If $\dim V = 2m$ is even, the same is true if and only if we have $\prod_v \epsilon_v = 1$, where for $v$ finite $\epsilon_v = 1$ if $G_v$ is quasi-split (including the case where $v$ is split in $E$), and $-1$ otherwise, and $\epsilon_v = (-1)^{p_v - m}$ if $v$ is real and $G_v = U(p_v, 2m - p_v)$.

1.4. Adelic points of $G$. Let $G$ be a unitary group as in the preceding §. Since the ring of adèles $\mathbb{A} = \mathbb{A}_F$ is an $F$-algebra (via the diagonal embedding), it make sense to talk of the group $G(\mathbb{A}_F)$. Since $G$ is linear, that is a subgroup of $GL_m$ for some $m$, $G(\mathbb{A}_F) \subset M_m(\mathbb{A}_F) = \mathbb{A}_F^{m \times m}$ which allots to give a natural topology on $G(\mathbb{A}_F)$, namely the coarsest that is finer that the topology of $\mathbb{A}_F^{m \times m}$ and for which $x \mapsto x^{-1}$
is continuous. This topology is easily seen to be independent of the choices. We shall need a good understanding of this group and of its natural topology.

Let $G$ be a model of $G$ over $\text{Spec} \mathcal{O}_F[1/f]$ where $f \in \mathcal{O}_F - \{0\}$, that is a group scheme over this scheme whose generic fiber is $G$. Then for all $v$ prime to $f$, the model define a subgroup $G(\mathcal{O}_v)$ of $G(F_v)$ which is compact when $v$ is finite. We can therefore form the restricted product $\prod_v' \text{places of } F G(F_v)$ with respect to the subgroups $G(\mathcal{O}_v)$.

**Lemma 1.1.** This restricted product with its restricted product locally compact topology is independent of the model $G$ chosen and is naturally isomorphic, as a topological group, with $G(\mathcal{A}_F)$.

The same lemma of course holds for the finite ad` eles $G(\mathcal{A}_F,f) = \prod_{v \text{ finite}}' G(F_v)$. We have $G(\mathcal{A}_F) = G(\mathcal{A}_F,f) \times G(\mathcal{A}_F,\infty)$.

The group $G(F)$ can be embedded diagonally in $G(\mathcal{A}_F)$. Its image is discrete. If $G$ is definite, then $G(F)$ is discrete in $G(\mathcal{A}_F,f)$ and the quotient is compact.

2. Representation of $p$-adic groups: a very brief review

In order to understand automorphic representations, we need to remind (without any proof) a very little part of the very important and still active theory of representations of $p$-adic Lie groups. For a serious introduction to this theory, see [Ca] or [Cas]

2.1. **Brief review on smooth representations.** In this § only, $G$ will be a group where there is basis of neighborhood of 1 made of compact open subgroups $U$.

**Exercise 2.1.** Prove that such a group is locally compact and totally disconnected. What about the converse?

Let $k$ be a field of characteristic 0. By a smooth representation $V$ of $G$ over $k$ we mean a $k$-vector space (not finite dimensional in general) with a linear action of $G$ such that for every $v \in V$, there exists a compact open subgroup $U$ in $G$ such that $v$ is invariant by $U$.

A smooth representation is admissible if for every open subgroup $U$ of $G$, the subspace $V^U$ of vectors invariant by $U$ is finite dimensional over $k$.

Let us fix a (left invariant, but since in practice our $G$ will be unimodular, this doesn’t really matter) Haar measure $dg$ on $G$, normalized such that the measure of some open compact subgroup $U_0$ is 1. Then is is easily seen that the measure of any other compact open subgroup will be a rational, hence an element in $k$.

We denote by $\mathcal{H}(G,k)$ the spaces of function from $G$ to $k$ that are locally constant and have compact support. This space as a natural product : the convolution of functions $(f_1 * f_2)(g) = \int_G f_1(x)f_2(x^{-1}g) \, dx$. Indeed, since $f_1$ and $f_2$ are in $\mathcal{H}(G,k)$, the integral is actually a finite sum, an what is more a finite sum of terms that
are products of a value of $f_1$, a value of $f_2$, and the measure of a compact open subgroup. So the integral really defines a $k$-valued function, and it is easy to check that $f_1 \ast f_2 \in \mathcal{H}(G,k)$. This product makes $\mathcal{H}(G,k)$ a $k$-algebra, which is not commutative if $G$ is not, and which in general has no unity (the unity would be a Dirac at 1, which is not a function on $G$ if $G$ is not discrete). If $V$ is a smooth representation of $G$ it has a natural structure of $\mathcal{H}(G,k)$-module by $f.v = \int_G f(g) g.v \, dg$. The algebra $\mathcal{H}(G,k)$ is called the algebra of the group $G$ over $k$.

Let $U$ be a compact open subgroup of $G$. Let $\mathcal{H}(G,U,k)$ be the set of functions form $G$ to $k$ that have compact support and that are both left and right invariant by $U$. This is easily seen to be a subalgebra of $\mathcal{H}(G,k)$, with unity (the unity is the characteristic function of $U$ times a normalization factor depending on the Haar measure). The algebra $\mathcal{H}(G,U,k)$ is called the Hecke algebra of $G$ w.r.t $U$ over $k$. We have $\mathcal{H}(G,k) = \bigcup_U \mathcal{H}(G,U,k)$ and in particular we see that if $G$ is not commutative, the $\mathcal{H}(G,U,k)$ are not for $U$ small enough. The Hecke algebra are important because of the following trivial property:

**Lemma 2.1.** Let $V$ be a smooth representation of $G$ (over $k$). Then the spaces of invariant $V^U$ has a natural structure of $\mathcal{H}(G,U,k)$-modules.

Indeed, if $v \in V^U \subset$, and $f \in \mathcal{H}(G,U,k) \subset \mathcal{H}(G,k)$, $f.v$ is easily seen to be in $V^U$.

If there is one thing to remember about Hecke algebras it is this lemma, not the definition: the Hecke algebra is what acts on $V^U$ when $V$ is a (smooth) representation of $G$ and $U$ sub-group of $G$.

We shall apply this theory to groups $G(F_v)$ when $G$ is a unitary group as above and $v$ is a finite place of $F$.

**Exercise 2.2. (easy)** Assume that $G$ is finite. Show that $\mathcal{H}(G,k)$ is naturally isomorphic with the algebra $k[G]$. Assume that $V$ is is a finite dimensional algebra. Show that the structures of $\mathcal{H}(G,k)$-module and $k[G]$-module on $V$ are compatible through that isomorphism.

Hence $\mathcal{H}(G,k)$ is a natural generalization of the classical group algebra of $G$ in the case of a finite $G$.

**Exercise 2.3. (easy)** Let $U$ be a normal open subgroup of $G$, and $V$ be an admissible representation of $U$. Show that $V^U$ is naturally an admissible representation of $G/U$. Hence $\mathcal{H}(G/U,k)$ acts on $V^U$. Show that $\mathcal{H}(G/U,k) = \mathcal{H}(G,U,k)$ and those two algebras have the same action on $V^U$.

Hence for non-normal $U$, the Hecke algebra $\mathcal{H}(G,U,k)$ is a generalization of the group algebra of $G/U$ for $U$ normal. In other words, when $U$ is non normal, we can not define $G/U$ as a group, but we do have a substitute for the group algebra of this non-existing group: $\mathcal{H}(G,U,k)$.
Exercise 2.4. Let $k'$ be an extension of $k$.

a. Show that if $V$ is a smooth representation of $G$ over $k$, then $V \otimes_k k'$ is a smooth representation of $G$ over $k'$.

b. Show that the formation of $V^U$ commutes to the extensions $k'/k$.

c. Show that $\mathcal{H}(G, U, k) \otimes_k k' = \mathcal{H}(G, U, k')$.

Exercise 2.5. Let $\mathcal{C}(G, k)$ and $\mathcal{C}(G/U, k)$ be the space of smooth functions from $G$ and $G/U$ to $k$.

a. Show that they both are smooth representation of $G$ (for the left translations)

b. Show $\mathcal{C}(G, k)^U = \mathcal{C}(G/U, k)$. Therefore $\mathcal{H}(G, U, k)$ acts on $\mathcal{C}(G, U, k)$. Show that this action commutes to the $G$-action.

c. Show that $\mathcal{H}(G, U, k)$ is actually naturally isomorphic to $\text{End}_G(\mathcal{C}(G/U, k))$.

Exercise 2.6. a. Show that $V \mapsto V^U$ is an exact functor form the category of smooth representation of $G$ over $k$ to $\mathcal{H}(G, U, k)$-module. This functor takes admissible representations to $\mathcal{H}(G, U, k)$ that are finite dimensional.

b. Let $W = V^U$, $W' \subset W$ a sub-$\mathcal{H}(G, U, k)$-module, and $V' \subset V$ the sub-representation of $V$ generated by $W'$. Show that $V'^U = W$.

c. Deduce that if $V$ is irreducible as a representation of $G$, then $V^U$ is irreducible as a $\mathcal{H}(G, U, k)$-module.

Note that in general the functor defined in a. above is not fully faithful (even on admissible rep.) and that the converse of c. is false.

2.2. Spherical Hecke algebras and unramified representations. We now assume that $F$ is a totally real field, $E$ an imaginary quadratic extension of $F$, and $G$ an unitary group of $n$-variables attached to $E/F$.

If $v$ is a finite place of $F$ that splits in $E$, then $G(F_v) \simeq \text{GL}_n(F_v)$. It is an easy fact that all maximal compact subgroups of $\text{GL}_n(F_v)$ are conjugate (and conjugate to $\text{GL}_n(O_v)$).

If $v$ is a finite place that does not split in $E$, then $G(F_v)$ is a true unitary groups.

It is not true that all maximal compact subgroups of $G(F_v)$ are conjugate, though there are only finitely many conjugacy class. If $v$ is inert, then there is one class whose elements have maximal volume (for a fixed Haar measure), and we call compacts of this class maximal hyperspecial compact subgroups of $G(F_v)$. We shall neglect places of $F$ that ramify in $E$ since there only in finite number.

Back to the case $v$ split, we shall call any maximal compact subgroup hyperspecial.

Proposition 2.1 (Tits). Let $\mathcal{G}$ be a model of $G$ over $\text{Spec}O_F[1/f]$. Then $\mathcal{G}(O_v)$ is a maximal compact hyperspecial subgroup of $G(F_v)$ for almost all finite places $v$. 
Corollary 2.1. Any compact open subgroup of $G(\mathbb{A}_f)$ contains a compact open subgroup of the form $\prod_v U_v$ with $U_v$ a compact open subgroup of $G(F_v)$ for all $v$, with $U_v$ maximal hyperspecial for almost all $v$.

Let $v$ be a place of $F$ (not ramified in $E$), and $K_v$ be a maximal compact hyperspecial subgroup of $G(F_v)$. Let $k$ be any field of characteristic 0.

Proposition 2.2. The algebra $\mathcal{H}(G(F_v), K_v, k)$ is commutative.

This fact is very important, and certainly not a tautology. As we have seen, $\mathcal{H}(G(F_v), U)$ will certainly be non commutative for small enough compact open subgroups. The fact that it is commutative for $K_v$ a well chosen maximal compact subgroup is what relates ultimately the theory of automorphic forms to commutative algebra, and is at the basis of all modern development ($R = T$, eigenvarieties, etc.) Instance of this phenomenon were first noticed by Poincaré in his paper on the shape of Saturn’s rings. The proposition above is due I guess, to Bruhat, and dates back to the early fifties.

Actually we can even determine the structure of the Hecke algebra $\mathcal{H}(G(F_v), K_v, k)$. We shall only need it in the case $v$ split, so $\mathcal{H}(G(F_v), K_v, k) = \mathcal{H}(GL_n(F_v), GL_n(O_v), k)$.

Proposition 2.3 (Satake). There exists an isomorphism of $k$-algebras

$$\mathcal{H}(GL_n(F_v), GL_n(O_v), k) \simeq k[T_1, \ldots, T_{n-1}, T_n, T_n^{-1}]$$

that sends $T_i$ to the characteristic function of

$$GL_n(O_v)\text{diag}(\pi, \ldots, \pi, 1, \ldots, 1)GL_n(O_v),$$

where the number of $\pi$’s is $i$.

Lemma and Definition 2.1. Let $V$ be a smooth irreducible representation of $G(F_v)$ over $k$, and $K_v$ a maximal hyperspecial subgroup of $G$. The statements $V^{K_v} \neq 0$ and $\dim_1 V^{K_v} = 1$ are equivalent. We call $V$ unramified if they hold.

Actually this lemma follows from the proposition 2.2 above as follows: we can easily (see exercise 2.4) reduce to the case $k$ algebraically closed and then since if $V$ is irreducible, $V^K$ is as a $\mathcal{H}(G, K_v, k)$-module (see exercise 2.6), hence has dimension one since the latter is commutative.

Here is an important observation: If $V$ is unramified, $V^{K_v}$ has dimension 1 and $\mathcal{H}(G(F_v), K_v, k)$ acts on $V^{K_v}$. Therefore, $V$ determines a character

$$\psi_{V,v} : \mathcal{H}(G(F_v), K_v, k) \to k.$$ (1)

It is a theorem (that we shall not use) that $V$ is uniquely determined by $\psi_{V,v}$.

The information containing in $\psi_{V,v}$ (that is the list of values $\psi_V(T_1), \ldots, \psi_V(T_n)$ in $k$, the latter being non-zero), can be summarized in a polynomial, the Satake polynomial.
Definition 2.1. The Satake polynomial of $V$ is the polynomial 
\[ P_{V,v}(X) = X^n - \psi_{V,v}(T_1)X^{n-1} + \psi_{V,v}(T_2)X^{n-2} - \cdots + (-1)^n\psi_{V,v}(T_n) \in k[X]. \]

Important caveat: This is not the correct normalization (for what follows). Actually coefficients should be multiplied by suitable integral power (or perhaps half-integral power) of the cardinality of the residue field. The correct form is to be found in Harris-Taylor’s book. Without access to this book here, this would be an excessive effort (so close to the beach) to retrieve the correct coefficients. I’ll put them after the conference.

Exercise 2.7. Prove Proposition 2.3 for $n = 2$, as follows. Replace first $\text{GL}_2(K_v)$ by $G = \text{PGL}_2(K_v)$ and $K$ by the image of $\text{GL}_2(O_v)$ in $G$. Proceed as follows:

a.– Construct an isomorphism of $G$-representations $\mathcal{C}(G/K, k) = \mathcal{C}(X, k)$ where $X$ is the tree of $\text{PGL}_2(K_v)$ defined in [B3] and $\mathcal{C}(X, k)$ the set of functions from $X$ to $k$ with finite support. Deduce (use Exercise 2.5) an isomorphism of algebras $\mathcal{H}(G, K, k) \simeq \text{End}_{k[G]}(\mathcal{C}(X, k))$.

b.– Let $T_1$ be the characteristic function of $K \text{diag}(\pi, 1)K$. Show that this element of $\mathcal{H}(G, K, k)$, seen as an operator on $\mathcal{C}(X, k)$ by the above isomorphism, sends a function $f$ on $X$ to the function $f'(x) = \sum_{y \text{ neighbor of } x} f(y)$.

c.– Deduce that $\mathcal{H}(G, K, k) = \mathbb{C}[T_1]$. Conclude.

3. Automorphic representations for $G$

We now fix a data $(F, E, V, q)$ as in the preceding § and we assume that the group $G$ is definite.

3.1. Automorphic forms.

Definition 3.1. A function $f : G(\mathbb{A}_F) = G(\mathbb{A}_{F,f}) \times G(\mathbb{A}_{F,\infty}) \to \mathbb{C}$ is said smooth, if it is continuous and if $f(g_f, g_\infty)$ is $\mathbb{C}^\infty$ as a function of $g_\infty$ (for $g_f$ fixed) and is locally constant with compact support as a function of $g_f$ (for $g_\infty$ fixed).

Definition 3.2. A function $f : G(\mathbb{A}_F) \to \mathbb{C}$ is called automorphic (or an automorphic form) if it is smooth, left-invariant by $G(F)$, and if it generates a finite dimensional spaces under $G(\mathbb{A}_{F,f})$. The space of all automorphic forms is called $A(G)$.

The space $A(G)$ has a natural hermitian product
\[ (f, f') = \int_{G(F) \backslash G(\mathbb{A}_F)} f(g)f'(g) \ dg, \]
which makes it a pre-Hermitian space (not a Hermitian space, since it is not complete). It has a natural action of $G(\mathbb{A}_F)$ by right translation, which preserves the hermitian product, so $A(G)$ is a pre-unitary representation.
3.2. Automorphic representations. An irreducible representation $\pi$ of $G(\mathbb{A})$ is said \textit{admissible} if, writing $\pi = \pi_f \otimes \pi_\infty$ where $\pi_f$ is an irreducible representation of $G(\mathbb{A}_f)$ and $\pi_\infty$ is an irreducible representation of $G(\mathbb{A}_\infty)$, then $\pi_f$ is admissible.

\textbf{Theorem 3.1.} The representation $A(G)$ is the direct sum of irreducible admissible representations of $G(\mathbb{A})$:

\begin{equation}
A(G) = \bigoplus_{\pi} m(\pi)\pi,
\end{equation}

where $\pi$ describes all the (isomorphism classes of) irreducible admissible representations of $G(\mathbb{A})$, and $m(\pi)$ is the (always finite) multiplicity of $\pi$ in the above space.

It will be convenient to denote by Irr the set (of isomorphism classes) of irreducible complex continuous (hence finite dimensional) representations of $G(\mathbb{A}_F, \mathbb{A}_\infty)$. For $W \in \text{Irr}$, we define $A(G, W)$ to be the $G(\mathbb{A}_F, \mathbb{A}_\infty)$-representation by right translation on the space of smooth vector valued functions $f : G(\mathbb{A}_F, \mathbb{A}_\infty) \to W^*$ such that $f(\gamma g) = \gamma_\infty f(g)$ for all $g \in G(\mathbb{A}_F, \mathbb{A}_\infty)$ and $\gamma \in G(F)$.

\textbf{Proof — (Sketch)} As $G(\mathbb{A}_F, \mathbb{A}_\infty)$ is compact the action of this group on $A(G)$ is completely reducible, hence as $G(\mathbb{A}_F) = G(\mathbb{A}_F, \mathbb{A}_\infty) \times G(\mathbb{A}_F, \mathbb{A}_\infty)$-representation we have:

\begin{equation}
A(G) = \bigoplus_{W \in \text{Irr}} W \otimes (A(G) \otimes W^*)^{G(\mathbb{A}_F, \mathbb{A}_\infty)}.
\end{equation}

But we check at once that the restriction map $f \mapsto f|_{1 \times G(\mathbb{A}_F, \mathbb{A}_\infty)}$ induces a $G(\mathbb{A}_F, \mathbb{A}_\infty)$-equivariant isomorphism

$$(A(G) \otimes W^*)^{G(\mathbb{A}_F, \mathbb{A}_\infty)} \simeq A(G, W).$$

As a consequence, the compactness of $G(F) \setminus G(\mathbb{A}_F)$ shows, by classical arguments that $A(G)$ is admissible, which together with the pre-unitariness of $A(G, W)$ proves the lemma.

\textbf{Definition 3.3.} An irreducible representation $\pi$ of $G(\mathbb{A})$ is said to be \textit{automorphic} if $m(\pi) \neq 0$.

Automorphic representations (for definite unitary groups) are always algebraic, in the following sense.

\textbf{Proposition 3.1.} If $\pi$ is automorphic, the representation $\pi_f$ has a model over $\bar{\mathbb{Q}}$.

\textbf{Proof — } Let $W \in \text{Irr}$ and let us restrict it to $G(F) \hookrightarrow G(\mathbb{A}_F, \mathbb{A}_\infty)$. As is well known $W$ comes from an algebraic representation of $G$, hence the inclusion $\bar{\mathbb{Q}} \subset \mathbb{C}$ equips $W$ with a $\bar{\mathbb{Q}}$-structure $W(\bar{\mathbb{Q}})$ which is $G(\bar{\mathbb{Q}})$-stable. As a consequence, the obviously defined space $A(G, W(\bar{\mathbb{Q}}))$ provides a $G(\mathbb{A}_f)$-stable $\bar{\mathbb{Q}}$-structure on $A(G, W)$, and the results follows.
Definition 3.4. We say that a compact open subgroup $U$ of $G(\mathbb{A}_f)$ is a level for an automorphic form $\pi$ if $\pi^U \neq 0$. Equivalently $\pi_f^U \neq 0$. Or we say simply that $\pi$ has level $U$. The weight of $\pi$ is simply the finite dimensional representation $\pi_{\infty}$.

Of course, if $U' \subset U$ and then if $\pi$ has level $U$ it has also level $U'$.

It is not hard to see that there exists only a finite number of automorphic representations with a fixed level and weight. (We shall not use it, but it fixes the ideas).

3.3. Decomposition of automorphic representations. Recall that if $(V_i)_{i \in I}$ is a family of vector spaces, with $W_i \subset V_i$ a given dimension 1 subspace defined for almost all $i$ (that is for all $i$ except for a finite set $J_0$ of $I$), then the restricted tensor product $\bigotimes'_{i \in I} V_i$ is defined as the inductive limit of $\bigotimes'_{i \in J} V_i \otimes \bigotimes_{i \in I \setminus J} W_i$ over the filtering set ordered by inclusion, of finite subsets $J$ (containing $J_0$) of $I$.

Theorem 3.2. Every admissible irreducible representation $\pi_f$ of $G(\mathbb{A}_F, f)$ can be written in a unique way as a restricted tensor product $\pi_f = \bigotimes'_{v \text{ finite place}} \pi_v$ where $\pi_v$ is a irreducible admissible representation of $G(F_v)$, and $\pi_v$ is unramified for almost all $v$. More precisely, if $\pi_f^U \neq 0$ where $U = \prod_v U_v$, then $\pi_v^U \neq 0$.

In particular, an automorphic representation $\pi = \pi_f \otimes \pi_{\infty}$ has components $\pi_v$ at all places $v$ of $F$: For finite $v$ these are the components $\pi_v$ of $\pi_f$ in the above sense, and for infinite $v$, simply the component of $\pi_{\infty}$ in the usual sense. If $\pi_f$ has level $U = \prod_v U_v$, with $U_v$ hyperspecial for all $v$ except those in a finite set of places $\Sigma$, then $\pi_v$ is unramified for $v \not\in \Sigma$.

4. Galois representations

4.1. set-up. Let $\pi$ be an automorphic representation of level $U$, and assume that $U$ contains $\prod_v U_v$. Let $\Sigma(U)$ be the set of places $v$ of $F$ such that

(i) the place $v$ splits in $E$

(ii) $U_v$ is a compact maximal (necessarily hyperspecial) of $G(F_v)$

If $v \in \Sigma(U)$, then $\pi_v$ is an unramified representation of $G(F_v)$, defined over $\overline{\mathbb{Q}}$.

The choice of one of the two places $w$ of $v$ defines an isomorphism (up to conjugacy) $G(F_v) \simeq \GL_n(F_v)$, so allows us to see $\pi_v$ as a well-determined up to isomorphism representation of $\GL_n(F_v)$. To such a representation one can attach its Satake polynomial, that we shall denote by $P_{\pi,w}(X)$.

4.2. Existence. The following theorem may now be considered as proven (even if some details have not yet appeared in print).

Let us fix an embedding of $\overline{\mathbb{Q}}$ into $\overline{\mathbb{Q}}_p$.

Theorem 4.1. Let $p$ be a prime. There exists a unique semi-simple Galois representations $\rho_{\pi} : G_E \to \GL_n(\overline{\mathbb{Q}}_p)$ such that at all places $v$ of $F$ in $\Sigma(U)$ such that $v$ does not divide $p$, then for the two places $w$ of $E$ above $v$, $\rho_{\pi}$ is unramified at $w$. 

and the characteristic polynomial of $\rho_{\pi}(\text{Frob}_w)$ has coefficients in $\bar{\mathbb{Q}}$ and is equal to $P_{\pi,w}$.

Note that the representation $\rho_{\pi}$ is a representation of $G_E$, not of $G_F$. Let us prove the uniqueness: The set of $w$ above a place in $\Sigma(\pi)$ has density one in $G_E$. Therefore by Cebotarev, the set of such $\text{Frob}_w$ in $G_E$ is dense, and in particular the character of $\rho_{\pi}$ is well determined by our condition. Therefore so is $\rho_{\pi}$ since it is assumed semi-simple. (the proof of existence is about five thousand times longer).

4.3. Properties. The representation $\rho_{\pi}$ enjoys many more properties. Let us give the most important ones.

(i) The non trivial automorphic $c \in \text{Gal}(E/F)$ induces by conjugation an outer automorphism of $G_E$, still denoted $c$. We have $\rho_{\pi}^c = \rho_{\pi}^*(1 - n)$. In particular $\rho_{\pi}$ is polarized in the sense of my notes on Bloch-Kato.

This is easy by looking at the form of the characteristic polynomials $P_{\pi,w}$ and $P_{\pi,w'}$ where $w$ and $w'$ are the two places above $v$, where $v$ is as in the theorem. Of course, I have not been explicit enough about the normalization so that you can check the details.

(ii) If $v$ is any place of $F$ where $\pi$ is unramified, and $w$ is a place of $E$ above $v$, then $\rho_{\pi}$ is unramified at $v$. (this is contained in the theorem for $v$ split, but this also true for $v$ inert.) In particular $\rho_{\pi}$ is unramified almost everywhere.

(iii) For $v$ split, and $w$ above $v$, the restriction of $\rho_{\pi}$ to $G_{E_w}$ corresponds by Local Langlands to the representation $\pi_v$ of $G(F_v)$ seen as a representation of $\text{GL}_n(F_v)$ using the isomorphism determined by $w$. This determines what happens at all split $v$, for $\pi$ unramified or not at $v$. (the analog statement for $v$ non-split is not known in full generality so far).

(iv) The representations $\rho_{\pi}$ is de Rham at all places dividing $p$ and the Hodge-Tate weights are determined by $\pi_{\infty}$. The representation $\rho_{\pi}$ is even crystalline at those places $w$ of $E$ that are unramified above places $v$ of $F$ such that $\pi_v$ is unramified. The crystalline Frobenius slope are determined by $\pi_{\infty}$ and $P_{\pi,w}$.

(v) The representation $\rho_{\pi}$ is geometric. (This follows from (ii) and (iv)). In most cases (technically, if $\pi_{\infty}$ is regular – see below), it is know by construction that $\rho_{\pi}$ actually comes from geometry. If $\rho_{\pi}$ is irreducible, it is pure of motivic weight, $1 - n$.

(vi) The $L$-function $L(\rho_{\pi}, s)$ satisfy all conjectures about $L$-functions sated in [B2](continuation, no zeros on the closure of the domain of convergence, no poles except in trivial cases, functional equation).

Note that $\rho_{\pi}$ is not irreducible in general. We can construct examples (endoscopic forms and C.A.P forms) of $\pi$ for which $\rho_{\pi}$ is reducible, and even some where its constituents have not all the same motivic weights (in those cases though, the set of
motivic weights is an arithmetic progression of ratio 1). However, for a large class of representations \( \pi \) called \textit{stable} (defined as those \( \pi \) whose base change to \( \text{GL}_n/E \) is cuspidal), it is expected that \( \rho_\pi \) is irreducible. It is known so far only if \( n \leq 3 \) (Blasius-Rogasky for \( n = 3 \)), \( n = 4 \) if \( F = \mathbb{Q} \) and \( \pi^c = \pi \) (Ramakrishna) or any \( n \) and \( E \) but \( \pi_v \) square integrable at some place \( v \) of \( F \) split in \( E \) (Taylor-Yoshida).

4.4. Hodge-Tate weights. We here explain how the weight \( \pi_\infty \) of \( \pi \) determine the HT weights of \( \rho_\pi \). For simplicity, we do so only in the case where \( F = \mathbb{Q} \) and \( p \) splits in \( F \). In this case \( \pi_\infty \) is simply a representation of the compact Lie group \( U(n)(\mathbb{R}) \), necessarily finitely dimensional.

If \( m := (m_1, \ldots, m_n) \in \mathbb{Z}^n \) satisfies \( m_1 \geq m_2 \geq \cdots \geq m_n \), we denote by \( W_m \) the rational (over \( \mathbb{Q} \)), irreducible, algebraic representation of \( \text{GL}_m \) whose highest weight relative to the upper triangular Borel is the character

\[
\delta_m : (z_1, \cdots, z_n) \mapsto \prod_{i=1}^n z_i^{m_i}.
\]

For any field \( F \) of characteristic 0, we get also a natural irreducible algebraic representation \( W_m(F) := W \otimes_{\mathbb{Q}} F \) of \( \text{GL}_n(F) \), and it turns out that they all have this form, for a unique \( m \).

Let us fix an embedding \( E \hookrightarrow \mathbb{C} \), which allows us to see \( U(n)(\mathbb{R}) \) as a subgroup of \( \text{GL}_n(\mathbb{C}) \) well defined up to conjugation (see Prop.1.1). So for \( m \) as above, we can view \( W_m(\mathbb{C}) \) as a continuous representation of \( U(n)(\mathbb{R}) \). As is well known, the set of all \( W_m(\mathbb{C}) \) is a system of representatives of all equivalence classes of irreducible continuous representations of \( U(m)(\mathbb{R}) \). We will say that \( W_m \) has \textit{regular weight} if \( m_1 > m_2 > \cdots > m_n \).

So by the above \( \pi_\infty = W_m(\mathbb{C}) \). The identification depends on an embedding of \( E \) to \( \mathbb{C} \) hence an embedding of \( E \) to the field \( \mathbb{Q} \) of algebraic number in \( \mathbb{C} \), hence via the chosen embedding of \( \mathbb{Q} \) into \( \mathbb{Q}_p \), an embedding \( E \hookrightarrow \mathbb{Q}_p \), that is a place \( w \) of \( E \) above \( p \).

**Proposition 4.1.** The Hodge-Tate weights of \( (\rho_\pi)|_{G_{E_w}} \) are \( k_1 = -m_1 + 1, k_2 = -m_2 + 2, \ldots, k_n = -m_n + n \).

Note that the Hodge-Tate weights are always distinct (this is a consequence of our working with a definite unitary group, analog to the fact that "modular forms of weight 1 (that is of HT weights 0 and 0) are not quaternionic modular forms"). When \( \pi_\infty \) is regular, two Hodge-Tate weights are never consecutive numbers.

**Exercise 4.1.** a.– If \( w' \) is the other place of \( E \) above \( p \), what are the Hodge-Tate weights of \( (\rho_\pi)|_{G_{E_w'}} \)?

b.– Is your answer conform to prediction 2.1 of [B2]?

---

\[1\] This means that the action of the diagonal torus of \( \text{GL}_n \) on the unique \( \mathbb{Q} \)-line stable by the upper Borel is given by the character above.
