International Taxation and the Location of Inventive Activity

ABSTRACT

This paper considers the effect of tax rules on the distribution of inventive activity between the United States and foreign countries. The empirical work analyzes the effect of U.S. tax changes on international patenting by a panel of American multinational firms. American firms differ in the extent to which they were affected by the R&D provisions of the Tax Reform Act of 1986. The evidence indicates that firms for which the after-tax cost of performing R&D in the United States for use abroad rose most rapidly after 1986 exhibit the slowest growth of foreign patenting in subsequent years. This pattern suggests that tax incentives influence subsequent patenting patterns of individual firms, and that foreign and domestic innovative activities are complements at the firm level.

1. Introduction.

Tax systems often encourage certain activities at the expense of others. Governments typically offer investments in research and development (R&D) very attractive tax treatment, since R&D is thought to be associated with large positive economic spillovers. One of the factors contributing to the generosity of tax benefits for R&D is competition between governments to attract R&D-intensive investments by multinational firms. Since a multinational firm typically has the option of performing its R&D in any of several countries, the volume of its R&D activity in one country is likely to be affected by the attractiveness of opportunities elsewhere. In spite of the frequency with which R&D receives generous tax subsidies, and the widespread belief that these subsidies encourage the discovery and development of new technologies, very little of a quantitative nature is known about the impact of tax rules on the international location of innovative activity.

The purpose of this paper is to examine the effect of taxation on the distribution of inventive activity between the United States and foreign countries. The paper analyzes the effect of U.S. tax changes, particularly those introduced by the Tax Reform Act of 1986, on the international pattern of subsequent patenting by American multinational firms. Due to the specifics of U.S. tax law, American firms differ in the extent to which tax changes affect the after-tax cost of performing R&D in the United States. Firms also differ in the extent to which tax changes affect the returns to using the results of R&D performed in the United States to generate sales abroad. The same U.S. tax changes do not directly influence the return to R&D

---

1 Griliches (1992) surveys the econometric evidence of economic spillovers from innovative activity.
performed abroad by American multinational firms, so any induced international relocation of innovative activity in the years following tax changes reflect the ways in which domestic and foreign patenting activity are related.

There is extensive interest in understanding the role that multinational firms play in transferring technologies across borders. There are two methods by which multinational firms provide technology to the countries in which they invest. The first method is to develop new technologies locally, through R&D or other similar types of activity. The second method is to import technologies produced elsewhere.

The foreign affiliates of American firms use both methods to bring technologies to the countries in which they invest, and there exists sufficient information to assess quantitatively the relative significance of each method. Direct information on the R&D activities of the foreign affiliates of American firms is reported in surveys conducted by the U.S. Commerce Department. Information on technology imports by these affiliates is considerably sketchier. One can, however, infer the approximate magnitude of technology imports from royalties paid by affiliates to American parent firms and third parties in other countries, since royalty payments should, in principle, reflect the values of imported technologies.

Table 1 reports detailed information on the aggregate technology-related behavior of the foreign affiliates of American firms in 1982, 1989, and 1994. It is noteworthy that affiliates paid more in royalties to their parent firms ($16.7 billion in 1994) than they spent on R&D ($11.9 billion in 1994), though, as the table indicates, there was extensive use of both methods of technology acquisition. The survey distinguishes two categories of R&D expenditure: R&D by
affiliates for themselves and R&D by affiliates for others. R&D by affiliates for themselves constitutes roughly 80 percent of their total R&D expenditures.

In spite of extensive consideration in the literature of the role that multinational firms play in facilitating international technology transfer,\(^2\) there is very little in the way of quantitative evidence of the complementarity or substitutability of foreign and domestic technology. Hines (1995) offers evidence that domestic and foreign R&D are substitutes, but to the extent that firms establish foreign R&D to exploit the core competencies that they have developed at home by adapting the firms’ technology to foreign markets, we would expect that foreign and domestic R&D would be complementary. The evidence reported in Hines (1995) is based on an analysis of aggregate data concerning the R&D activities of American multinational firms abroad and the R&D activities of foreign investors in the United States. The purpose of the current investigation is to examine whether similar patterns appear at a firm level.

The empirical results in this paper suggest that foreign and domestic innovative activities are complements rather than substitutes. Specifically, firms with rising after-tax costs of performing R&D in the United States that is directed at generating technology for use abroad are those that exhibit the slowest growth of foreign patenting. This pattern is sensible if the willingness to undertake foreign R&D is a function of the propensity to perform related domestic R&D, and the latter is a function of domestic tax incentives. What the results indicate is that

\(^2\) See, for example, Teece (1976), Mansfield, Teece, and Romeo (1979), Mansfield and Romeo (1980), Davidson and McFetridge (1984), Lipsey, Blomstrom, and Kravis (1990), Zejan (1990), Blomstrom (1991), Wang and Blomstrom (1992), Blomstrom and Kokko (1995), and Ethier and Markusen (1996). These studies together consider the effect of a large number of variables on technology transfer and R&D activity, though they do not consider the potential complementarity of domestic and foreign innovation.
domestic tax incentives can significantly influence not only the rate of domestic innovation, but also the rate of foreign innovation by American multinational firms. Since complementarity is a symmetric relationship, the results also imply that foreign tax incentives should influence the rate at which American multinational firms innovate in their domestic markets.

Evidence of the complementarity of innovative activity comes from an analysis of the behavior of a panel of American multinational firms over the 1982-1992 period. There were several important U.S. tax changes over this time period, notable among them the changes introduced by the Tax Reform Act of 1986. Using international patent data that specify the inventor’s country of residence, it is possible to trace the effect of U.S. tax changes on subsequent patenting patterns, and thereby to identify any effects of U.S. tax changes on foreign innovative activity (as reflected by patents).

Section 2 of the paper reviews the U.S. tax treatment of foreign-source income, with an emphasis on the tax treatment of R&D expenses and foreign royalty receipts. Section 3 presents a model of firm behavior and describes the data used in the empirical analysis. Section 4 presents the regression results and analyzes their implications. Section 5 is the conclusion.

2. **Tax incentives.**

The United States taxes income on a residence basis, meaning that American corporations and individuals owe taxes to the U.S. government on all of their worldwide income. The top U.S. corporate tax rate is now 35 percent. Since profits earned in foreign countries are usually
taxed by host governments, U.S. law permits taxpayers to claim tax credits for foreign income taxes and related tax obligations, in order not to subject American multinationals to double taxation. The foreign tax credit mechanism implies that a U.S. corporation earning $100 in a foreign country with a 12 percent tax rate (and a foreign tax obligation of $12) pays only $23 to the U.S. government, since its U.S. corporate tax liability of $35 (35 percent of $100) is reduced to $23 by the foreign tax credit of $12. The foreign tax credit is, however, limited to U.S. tax liability on foreign income; if, in the example, the foreign tax rate were 50 percent, then the firm pays $50 to the foreign government but its U.S. foreign tax credit is limited to $35. Hence an American firm receives full tax credits for its foreign taxes paid only when it is in a deficit credit position, i.e., when its average foreign tax rate is less than its tax rate on domestic operations. A firm has excess credits if its available foreign tax credits exceed U.S. tax liability on its foreign income. Firms average together their taxable incomes and taxes paid in all of their foreign operations in calculating their foreign tax credits and the foreign tax credit limit.4

Deferral of U.S. taxation of certain foreign earnings is another important feature of the U.S. international tax system. An American parent firm is taxed on its subsidiaries' foreign income only when repatriated to the parent corporation. This type of deferral is available only to foreign operations that are separately incorporated in foreign countries (subsidiaries of the

---

4 In order to qualify for the foreign tax credit, firms must own at least 10% of a foreign affiliate, and only those taxes that qualify as income taxes are creditable. Furthermore, income is broken into different functional "baskets" in the calculation of applicable credits and limits. Income earned and taxes paid in the conduct of most types of active foreign business operations are grouped in one "basket;" petroleum industry income is grouped in a separate "basket;" and there are separate "baskets" for items such as passive income earned abroad. The "basket" distinctions imply that a firm might simultaneously have excess foreign tax credits in the petroleum "basket" (which is common, since foreign tax rates on
parent) and not to consolidated (branch) operations. The U.S. government taxes branch profits as they are earned, just as it would profits earned within the United States.

The deferral of U.S. taxation may create incentives for firms with lightly-taxed foreign earnings to delay repatriating dividends from their foreign subsidiaries.\(^5\) This incentive arises in those cases in which firms expect never to repatriate their foreign earnings, or if they anticipate that future years will be more attractive for repatriation (either because domestic tax rates will be lower, or because future sources of foreign income will generate excess foreign tax credits that can be used to offset US tax liability on the dividends).\(^6\) It appears that, in practice, U.S. multinationals choose their dividend repatriations selectively, generally paying dividends out of their more heavily taxed foreign earnings first.\(^7\) Consequently, the average tax rate that firms face on their foreign income need not exactly equal the average foreign tax rate faced by their branches and subsidiaries abroad.

Branch earnings and dividends from subsidiaries represent only two forms of foreign income for U.S. income tax purposes. Interest received from foreign sources also represents foreign income, though foreign interest receipts are often classified within their own "basket" and

---

\(^5\)The incentive to defer repatriation of lightly taxed subsidiary earnings is attenuated by the Subpart F provisions, introduced in U.S. law in 1962, that treat a subsidiary's passive income, and income invested in U.S. property, as if it were distributed to its American owners, thereby subjecting it to immediate U.S. taxation. The Subpart F rules apply to controlled foreign corporations, which are foreign corporations owned at least 50% by U.S. persons holding stakes of at least 10% each. Controlled foreign corporations that reinvest their foreign earnings in active businesses can continue to defer their U.S. tax liability on those earnings. See Hines and Rice (1994) and Scholes and Wolfson (1991) for the behavioral implications of these rules.

\(^6\)It is interesting to note that the deferral of U.S. tax liability does not itself create an incentive to delay paying dividends from foreign subsidiaries, since the U.S. tax must be paid eventually. See Hartman (1985).

\(^7\)See the evidence presented in Hines and Hubbard (1990), Altshuler and Newlon (1993), and Altshuler et al. (1995).
hence are not averaged with other income in calculating the foreign tax credit. Royalty income received from foreigners, including foreign affiliates of U.S. firms, is also foreign source income. Foreign governments often impose moderate taxes on dividend, interest, and royalty payments from foreign affiliates to their American parent companies; these withholding\(^8\) taxes are fully creditable against an American taxpayer's U.S. tax liability on foreign income.

Royalties received by American parent firms for R&D used abroad represent taxable foreign-source income of the American firms. American firms with deficit foreign tax credits must pay U.S. income tax on these royalty receipts, while firms with excess foreign tax credits can apply the excess credits against U.S. taxes due on the royalties, thereby eliminating the U.S. tax liability created by the royalty receipts.

Most of the world's governments impose withholding taxes on cross-border royalty payments from affiliates located within their countries. These royalty tax rates are frequently reduced according to the terms of bilateral tax treaties. For example, the United States imposes a 30 percent tax on royalties paid to foreign corporations, but this tax rate is often reduced, in some cases to zero, when recipients of royalty payments are located in countries with whom the United States has a tax treaty in force.

**Interaction of R&D and Foreign Income Rules**

\(^8\)Taxes on cross-border flows, such as dividends, interest, and royalties, are known as "withholding" taxes due to some of the niceties of their administration. Strictly speaking, these taxes represent obligations of the recipients and not the payors; this arrangement permits immediate crediting of withholding taxes by recipients who are eligible to claim foreign tax credits. The taxes are called "withholding" taxes because the local payor is the withholding agent for the tax, and is therefore liable to ensure that the taxes are paid.
American firms with foreign income are generally not permitted to deduct all of their R&D expenditures in the United States against their domestic taxable incomes. Instead, the law provides for various methods of allocating R&D expenses between domestic and foreign income. The intention of the law is to retain the relatively generous treatment of R&D, but only for that part of a firm's R&D expenditures that is devoted to production for domestic markets. R&D-performing firms with foreign sales and foreign income are presumed to be doing at least some of their R&D to enhance their foreign profitability.

From the standpoint of taxpaying firms, the U.S. tax law's distinction between domestic and foreign R&D deductions is potentially quite important. If an R&D expense is deemed to be domestic, then it is deductible against the taxpayer's U.S. taxable income. Alternatively, if it is deemed to be foreign, then the R&D expense reduces foreign taxable income for the purposes of U.S. income taxation only. Foreign governments do not use U.S. methods of calculating R&D deductions, and generally do not permit American firms to reduce their taxable incomes in foreign countries on the basis of R&D undertaken in the United States. Consequently, an R&D expense deduction allocated against foreign income is valuable to an American firm only if the firm has deficit foreign tax credits. If the firm has deficit credits, then the firm pays some U.S. tax on its foreign income, and any additional dollar of R&D deduction allocated against foreign income reduces the firm's US taxable income by a dollar. Hence, firms with deficit foreign tax credits are indifferent between allocating R&D expenses against foreign income and allocating
them against domestic income. By contrast, firms with excess foreign tax credits pay no U.S.
tax on their foreign income, and therefore have no use for R&D deductions allocated against
foreign income. Consequently, firms with excess foreign tax credits lose the value of any R&D
deductions allocated against foreign income.

The tax law governing the allocation of R&D expenses was for years rather vague, but
was codified by U.S. Treasury Regulation section 1.861-8 in 1977. The 1977 rules provide for
several stages in allocating R&D expenditures for tax purposes. R&D in the United States that is
undertaken to meet certain legal requirements (such as R&D devoted to meeting pollution
standards) can be 100% allocated against domestic income. Firms that perform more than half of
their [other than legally required] R&D in the United States are permitted to allocate 30% of that
R&D against U.S. income. The remaining 70% is then to be allocated between domestic and
foreign sources on the basis of sales (including the sales of controlled foreign corporations).
R&D is generally allocated according to activities within product lines (defined similarly to two-
digit SIC codes), so that a corporation need not allocate part of its chemical R&D against foreign
income simply because the electronics part of its business has foreign sales.

There are several options available to taxpayers who are unsatisfied with the outcome of
the R&D allocation method just described. Firms are permitted to apportion more than 30% of
their domestic R&D against U.S. income if they can establish that it is reasonable to expect the

---

9This statement, along with much of the subsequent analysis, abstracts from the ability of firms to carry excess foreign
tax credits backward two years and forward five years. Firms that can exploit carryforwards or carrybacks may
(depending on specific circumstances) face incentives that are intermediate between those of deficit credit and excess
credit firms.
R&D so apportioned to have very limited application outside of the country; the remaining portion of its R&D expenses are then allocated on the basis of sales. Alternatively, firms are permitted to allocate their R&D on the basis of total foreign and domestic income (though without the 30% initial allocation to U.S. source), so that firms with foreign operations that generate sales but not income (relative to domestic operations) might prefer the income allocation method. There is, however, a limit to the income allocation method: firms are not permitted to reduce their foreign source R&D expense allocation to less than 50% of the allocation that would have been produced by the sales method (including the 30% initial apportionment).

The Economic Recovery Tax Act in 1981 changed these rules by permitting American firms to allocate 100% of the expense of R&D performed in the United States against U.S. taxable income. This change was intended to be temporary (two years), in order to offer strong R&D incentives while affording Congress the opportunity to rethink its R&D policy. At the end of that time, the U.S. Department of the Treasury produced a study (1983) concluding that the tax change offered a small R&D incentive to U.S. firms, and was desirable on that basis.\textsuperscript{10} In 1984 and 1985 the Congress extended the temporary change permitting 100% deductibility of U.S. R&D expenses against U.S. income, so these rules remained in place until the end of the 1986 tax year.

The Tax Reform Act of 1986 removed the 100% deductibility of U.S. R&D expenses,

\textsuperscript{10}The Treasury study (1983) based its conclusions on a range of assumed elasticities of R&D with respect to price changes; there was no attempt made to ascertain how firms responded to the changes introduced in 1981.
replacing it with a new, and again temporary, system of R&D expense allocation.\footnote{The Tax Reform Act of 1986 also introduced a number of other changes relevant to R&D investment decisions, including reducing the statutory corporate tax rate from 46\% (the tax rate from 1979-1986) to 40\% in 1987 and 34\% for 1988 and subsequent years. The 1986 Act also removed a number of investment incentives such as accelerated depreciation of capital assets and the investment tax credit for new equipment purchases.} Under the 1986 Act, 50\% of U.S. R&D expense (other than R&D to meet regulations, which was 100\% allocated to domestic source) was allocated to domestic source, with the remaining 50\% allocated on the basis of sales or of income, at the taxpayer's choice. There was no limit imposed on the degree to which allocation on the basis of gross income could reduce foreign allocation relative to the sales method. These rules, it turned out, were in effect only for 1987.

The Technical and Miscellaneous Revenue Act of 1988 changed the R&D expense allocation rules for the first part of 1988. For the first four months of the year firms were permitted to allocate 64\% of U.S. R&D expense against U.S. domestic income, with the remaining 36\% allocated between foreign and domestic sources on the basis of either sales or income (at the taxpayer's choice). The 1988 Act further provides that if the 36\% were allocated on the basis of income, then the R&D allocation against foreign income must equal at least 30\% of the foreign allocation that would have been produced by the sales method. For the remaining eight months of the year, taxpayers were required to use the allocation method described in section 1.861-8 as of 1977 (and described above).

The Omnibus Budget Reconciliation Act of 1989 again changed the R&D allocation rules, this time reintroducing the same rules that applied for the first four months of 1988. The Omnibus Budget Reconciliation Act of 1990 and the Tax Extension Act of 1991 extended this
treatment of R&D expenses until a date that depends on a taxpayer's choice of fiscal year, but in no case later than 1 August 1992. Consequently, 64% of domestically-performed R&D in 1989-1992 could be allocated against domestic income, with the remaining 36% allocated either on the basis of sales or of income (though use of the income method could not reduce foreign source allocation to less than 30% of the foreign source allocation that would have been produced by the sales method).

The expiration of the R&D expense allocation legislation in the summer of 1992 motivated an extensive reconsideration of the issue of the appropriate tax treatment of R&D expenditures by multinational firms. In June 1992, the Treasury temporarily suspended its section 1.861-8 allocation rules (the 1977 regulations), replacing them with an 18-month moratorium in which taxpayers could continue to use the system embodied in the legislation covering the years 1989-1992 (64% place-of-performance allocation, with the remaining deductions allocated on the basis of sales). The idea was that the Treasury would reexamine its section 1.861-8 regulations during the 18-month period. The rationale for the moratorium was "to provide taxpayers with transition relief and to minimize audit controversy and facilitate business planning during the conduct of the regulatory review." Some contemporaneous observers noted that the extension of the R&D allocation rules through Treasury moratorium instead of Congressional legislation made the rules less costly from the standpoint of federal budget targets, since regulatory changes are exempt from the budget agreement limits. What role, if any, such considerations played in the decision to suspend the section 1.861-8 rules is not
clear. In any case, the Treasury moratorium did not run its full course, being supplanted in 1993 by new legislation.

President Clinton's budget proposal of February 1993 recommended a major change in the allocation of R&D expenditures and treatment of royalty receipts by U.S.-based multinational corporations. The President proposed that American firms deduct 100% of their U.S. R&D expenditures against U.S. income, but that the same firms no longer be permitted to use foreign tax credits generated by their active foreign operations to reduce U.S. tax liabilities on royalty income from foreign sources. Instead, firms would be required to allocate foreign-source royalty income to the "passive basket" in determining their foreign tax credit limits. The idea behind the change was to limit severely the ability of American firms to use excess foreign tax credits to wipe out their U.S. tax liabilities on foreign-source royalty income. Very few firms have excess foreign tax credits in the "passive basket." Consequently, the overall effect of the proposal would have been to raise the deductions that firms with excess foreign tax credits receive for R&D performed in the United States, but to include - as income fully taxed by the United States - the royalties they receive from foreign sources. Congress chose not to include this proposal in the legislation passed in August 1993.

Instead, the Omnibus Budget Reconciliation Act of 1993 (OBRA 93) continued the pattern of allowing U.S.-based multinational firms to deduct only a fraction of their U.S. R&D expenses against U.S. income, and, at the same time, permits firms to use excess foreign tax credits to eliminate U.S. tax liabilities on foreign-source royalty income. OBRA 93 permitted

---

firms to allocate 50% of U.S.-based R&D expenses to domestic source, with the remaining 50% allocated between domestic and foreign source based either on sales or on income, at the taxpayer's option (subject to the restriction that income-based allocation not reduce foreign source allocation to less than 30% of that produced by the sales method). The allocation rules under OBRA 93 were temporary, expiring one year after they took effect. As in earlier years, many observers attributed the temporary nature of the allocation rules to the mechanics of compliance with federal budget targets: if Congress were to pass permanent legislation covering the R&D allocation rules, then the "cost," to the current-year budget, of any treatment more generous than the 1977 regulations, must include "costs" incurred in future years. By instead passing temporary legislation, Congress incurs budgetary "costs" only for the current year. Of course, budgetary "costs" need not bear any relation to the economic consequences of permanent legislation covering the allocation of R&D expenses.13

During 1995 the Treasury reconsidered the appropriateness of its 1977 R&D expense regulations. Based on newer analysis (U.S. Department of the Treasury, 1995), the regulations were amended roughly along the lines of recent legislative developments. Specifically, the 1995 regulations permit firms to select one of two allocation methods, one in which firms allocate 50% of U.S.-based R&D expenses to domestic source, with the remaining 50% allocated between domestic and foreign source based on sales, and a second in which firms allocate 25% of U.S.-

13There are some with strong feelings that permanent legislation creates a more predictable environment for businesses, thereby making the United States a more attractive location for R&D. Turro (1993, p. 436) quotes one tax practitioner, who describes the Congress’s decision to make the OBRA 93 R&D allocation rules temporary an "absurd tax policy decision."
based R&D expenses to domestic source, with the remaining 75% allocated between domestic and foreign source based on gross income. Under these regulations, income-based allocation is not permitted to reduce foreign source allocation to less than 50% of that produced by the sales method. The new regulations amend the previous rules in certain, more minor, ways as well.\textsuperscript{14} Since the OBRA 93 R&D allocation rules have now expired, the 1995 Treasury regulations now govern the allocation of U.S. R&D expenses.\textsuperscript{15}

3. Framework for analysis.

Changes in the U.S. tax treatment of R&D expenses affect some firms more than others, due to differences in excess foreign tax credit status and in the extent to which sales and income have foreign sources. Consequently, these changes can be used to identify differences between firms in costs of performing R&D in the United States in years before and after tax changes. The idea behind the empirical work that follows is to draw appropriate inferences from correlations between tax-driven cost changes and subsequent propensities to take out patents on the basis of U.S. and foreign research activities.

3.1 A model.

\textsuperscript{14}Specifically, firms are required to make their elections permanent, so it is not possible to use the sales method in one year and the income method in the next. In addition, the new regulations specify that firms allocate R&D expenses based on 3-digit SIC activities, rather than the 2-digit SIC activities provided in the previous regulations.

\textsuperscript{15}It is noteworthy that the 1995 revisions to the R&D cost allocation regulations were not "costly" from the standpoint of federal budget targets, since regulatory changes are not budgeted.
It is useful to distinguish three types of R&D undertaken by multinational firms. The first type is R&D performed in the United States and intended to produce innovative output for the American market. The second type is R&D performed in the United States and intended to generate foreign sales. The third type is R&D performed abroad. Tax incentives differ for each of these types, and as a result, the incentives that firms face to undertake R&D in domestic and foreign locations will differ. Of course, to a certain degree these distinctions may be more pronounced ex post than they are ex ante, since, in the early stages of industrial research, the location of ultimate sales may be more than a little bit uncertain. For the purpose of this analysis, firms are assumed to be able to distinguish the ultimate location of the uses of their innovative output at the time that they perform the initial R&D.

The R&D expense allocation rules imply that multinational firms performing R&D in the United States are unable to deduct all of their R&D expenses in years after 1986. Instead, they can deduct a fraction $\alpha$ of such expenses, in which the value of $\alpha$ depends on the firm’s foreign tax credit status, its ratio of foreign to domestic sales, and the tax rules in place at the time. U.S. tax rules in effect between 1981-1986 imply that $\alpha = 1$, while those in effect after 1986 imply that $1 \geq \alpha \geq 0$.

An American firm that contemplates committing funds to an R&D project that is expected to generate innovative output, and therefore sales in the domestic market, maximizes:

\[ \pi_i = Q(R_i, 2_i)(1-\tau) - R_i(1-\alpha\tau), \]
in which \( \pi_i \) denotes firm i’s after-tax profits, \( R_i \) is firm i’s expenditures on R&D, \( Q(A) \) is net sales generated by firm i’s R&D activity, \( \forall i \) is the fraction of firm i’s R&D expenses that are deductible for tax purposes, and \( \tau \) is the statutory tax rate. The variable \( 2_i \) is an unobservable parameter (assumed to be known to firms) that affects the productivity of firm i’s research activity and thereby influences its desired R&D spending. The function \( Q(A) \) is assumed to be twice continuously differentiable and concave in \( R \). The first-order condition corresponding to an interior maximum of (1) is \( \frac{\partial \pi_i}{\partial R_i} = 0 \), which implies:

\[
(2) \quad \frac{\partial Q(R_i, \theta_i)}{\partial R_i} = \frac{1 - \alpha_i \tau}{1 - \tau}.
\]

Equation (2) expresses the simple point that reduced deductibility of domestic R&D expenses, which is captured by lower values of \( \alpha_i \), are associated with higher required marginal products of R&D expenditures by profit-maximizing firms. Since the function \( Q(A) \) is assumed to exhibit decreasing returns to \( R \), it follows that lower values of \( \alpha_i \) reduce desired spending on R&D.

The incentives facing an American multinational firm performing R&D in the United States for use abroad are potentially quite different. Returns to the innovating firm come in the form of foreign-source royalties that are effectively untaxed by the United States if the firm has excess foreign tax credits, and are fully taxed otherwise. Denoting firm i’s R&D undertaken for this purpose by \( R_i^* \), and the relevant sales function by \( Q^*(R_i^*, 2_i) \), \(^{16}\) the firm’s profits from this

---

\(^{16}\) Strictly speaking, it is necessary for the analysis that follows to include as an argument of the \( Q^*(A) \) function R&D
source ($\pi_i^*$) equal:

\begin{equation}
\pi_i^* = Q^*(R_i^*, \theta_i) (1 - \beta_i \tau) - R_i^* (1 - \alpha i \tau),
\end{equation}

in which $\beta_i$ reflects the extent to which firm $i$’s foreign-source royalties are taxed, so that $\beta_i = 0$ for firms with excess foreign tax credits and $\beta_i = 1$ for firms with deficit foreign tax credits.

The first-order condition corresponding to an interior maximum of (3) with respect to $R_i^*$ is $\partial \pi_i^*/\partial R_i^* = 0$, implying:

\begin{equation}
\frac{\partial Q^*(R_i^*, \theta_i)}{\partial R_i^*} = \frac{1 - \alpha_i \tau}{1 - \beta_i \tau}.
\end{equation}

Equation (4) expresses in a simple way that the incentive to perform R&D in the United States for use abroad is a function of the deductibility of R&D expenses as well as the tax treatment of foreign-source royalty receipts. Assuming the $Q^*(\cdot)$ function to exhibit decreasing returns to $R^*$, it follows that the desired level of $R^*$ is an increasing function of $\forall$ and a decreasing function of $\exists$.

The third type of R&D that multinational firms undertake is foreign R&D. The foreign innovative activity of American multinational firms is a decreasing function of R&D performed undertaken by foreign affiliates; this argument is omitted, since including it complicates the notation without changing the interpretation of the results.
in the United States and intended for foreign use \((R^*)\) if foreign and domestic research are substitutes, and an increasing function of \(R^*\) if they are complements.\(^{17}\) Since \(R_t^*\) is not directly observable, it is necessary to infer its value from the tax incentives that firm \(i\) faces. This inference is greatly complicated by the likely importance of firm-specific technology shocks. Firms differ greatly in their abilities and willingness to patent new technologies, and these differences may change over time. It is convenient to introduce the variable \(\phi_{it}\), which denotes a firm-specific shock to the patenting proclivity of firm \(i\) in period \(t\). The firm-specific shock \(\phi_{it}\) differs from \(2_{it}\), in that \(2_{it}\) affects the marginal product of additional R&D spending, while \(\phi_{it}\) affects the proclivity to obtain patents conditional on research activity.

It is helpful to define foreign and domestic patenting functions:

\[
\begin{align*}
(5a) \quad P_{it}^* &= P^*(R_{it}^f, \phi_{it}) \\
(5b) \quad P_{it} &= P(R_{it}, \phi_{it})
\end{align*}
\]

in which \(R_{it}^f\) is the foreign R&D spending of firm \(i\) in year \(t\), \(P_{it}^*\) is the number of foreign patents taken out by firm \(i\) in year \(t\), and \(P_{it}\) is the corresponding number of domestic patents.\(^{18}\)

\(^{17}\) This discussion takes the returns to foreign R&D to be unaffected by domestic R&D intended for the domestic market. This is a reasonable assumption, given the very limited domestic use of technology produced by foreign affiliates, as reflected by royalty payments reported in Table 1.

\(^{18}\) It is noteworthy that this specification assumes that any technology spillovers between domestic and foreign innovation are fully credited to proper sources and therefore reflected in royalty payments. The functional forms of (5a) and (5b) also require that patenting be affected only by R&D performed contemporaneously, a testable proposition examined in the next section.
From (4) it is clear that the after-tax cost of domestic R&D directed at producing sales in foreign markets is a function of the firm’s domestic tax situation. The extent, therefore, to which these domestic tax considerations affect $R_{it}^{f}$ (and thereby affect $P_{it}^{*}$) depends on the complementarity or substitutability of foreign and domestic technology. The firm’s derived demand for foreign R&D can be written:

$$R_{it}^{f} = g^{*}\{\frac{(1-\alpha_{it}\tau_{t})}{(1-\beta_{it}\tau_{t})}, 2_{it}\},$$

in which the first argument of the $g^{*}$ function is simply the after-tax cost of performing R&D at home to generate sales abroad, and other considerations, such as firm and economy characteristics in year $t$, are captured by $2_{it}$.

Combining (5a) and (6) yields a function that expresses foreign patenting as it is affected by the price of domestic R&D:

$$P_{it}^{*} = h^{*}\{\frac{(1-\alpha_{it}\tau_{t})}{(1-\beta_{it}\tau_{t})}, 2_{it}, \phi_{it}\}.$$

By a similar reasoning, the demand for domestic R&D directed at producing sales in the domestic market is a function of the implied after-tax cost indicated by (2):

$$R_{it} = g\{\frac{(1-\alpha_{it}\tau_{t})}{(1-\tau_{t})}, 2_{it}\},$$
which, combined with (5b), implies:

\begin{equation}
(9) \quad P_{it} = h\{[(1-\alpha_{it}\tau_t)/(1-\tau_t)], 2it, \phi_{it}\}.
\end{equation}

Linearizing the effect of $2$ and $\phi$ yields:

\begin{equation}
(10) \quad P^*_{it} = f^*[(1-\alpha_{it}\tau_t)/(1-\beta_{it}\tau_t)] + c^*(2it + \phi_{it}),
\end{equation}

and

\begin{equation}
(11) \quad P_{it} = f[(1-\alpha_{it}\tau_t)/(1-\tau_t)] + c(2it + \phi_{it}).
\end{equation}

Combining (10) and (11), and taking first differences, yields:

\begin{equation}
(12) \quad P^*_{it} - P^*_{it-1} = *_{1it} - (c^*/c)*_{2it} + (c^*/c)(P_{it} - P_{it-1}),
\end{equation}

\[
*_{1it} / f^*[(1-\alpha_{it}\tau_t)/(1-\beta_{it}\tau_t)] - f^*[(1-\alpha_{it-1}\tau_{t-1})/(1-\beta_{it-1}\tau_{t-1})] \\
*_{2it} / f[(1-\alpha_{it}\tau_t)/(1-\tau_t)] - f[(1-\alpha_{it-1}\tau_{t-1})/(1-\tau_{t-1})].
\]

Equation (12) expresses the change in foreign patenting as a function of three variables: the change in home-country tax incentives for home R&D directed at foreign markets, the change
in tax incentives for home R&D directed at domestic markets, and the change in domestic patenting. Estimates of the propensity to develop foreign patents as a function of these variables implicitly estimate the degree of complementarity or substitutability of foreign and domestic R&D, since this connection is embedded in the $f^*(A)$ function. It is this specification that provides the framework used in the empirical analysis.

3.2 Data.

The empirical work that follows analyzes the behavior of publicly-traded firms whose annual report information is collected by Compustat. Starting from a universe of somewhat over 7,500 companies, firms are included in the sample if they are multinationals incorporated in the United States, and if their reported foreign assets equal one percent or more of reported total assets for each year during 1986-1990. This criterion is satisfied by 422 firms.

Foreign tax rate information is central to the analysis, since the hypothesis that firms maximize after-tax profits implies that deficit foreign tax credit firms will react very differently than excess foreign tax credit firms to the changes introduced by the Tax Reform Act of 1986. Compustat reports foreign pretax incomes and foreign taxes paid by the firms in the sample, from which it is possible to use simple division to obtain an estimate of effective foreign tax rates.¹⁹

¹⁹ Average foreign tax rates are used in place of actual foreign tax credit status (i.e., excess or deficit credit) for two reasons. The first reason is that actual foreign tax status is endogenous to a host of decision variables related to the financing, investment, repatriation, transfer pricing, and other activities of multinational firms. While average foreign tax rates are, by the same reasoning, also endogenous, the endogeneity problem is generally regarded to be more severe with excess foreign tax credit status than it is with average foreign tax rates. The second reason is that tax return data at the firm level are unavailable, so the actual foreign tax credit situations of firms in the sample cannot be determined.
These average foreign tax rates for firms in 1985 are the basis of the tax calculations that follow. Data for 1985 are used because this was the last full year before passage of the Tax Reform Act of 1986, which introduced incentives to relocate foreign operations and tax liabilities. Average foreign tax rates are truncated at zero and 100% for purposes of this construction.

During the 1983-1986 period, U.S. tax law permitted American firms to deduct 100% of their domestic R&D expenses against domestic taxable income. In the years after 1986, deductibility is based on excess foreign tax credit status and on shares of total sales in foreign markets. For the purposes of constructing regression variables, $\alpha_{it}$ is assigned a value of one for all firms until 1986. In the period after 1986, firms are assigned $\alpha_{it} = 1$ if the 1985 foreign average tax rate is below the (year t) U.S. statutory tax rate, and otherwise $\alpha_{it} = [1 - 0.36(\text{foreign sales fraction})]$, corresponding to the expense allocation rules in place in 1991. Since the value of $\beta_{it}$ depends critically on foreign tax credit status about which only imprecise information is available, a more continuous tax specification is used in defining $\beta_{it}$: $\beta_{it}$ is defined to equal one minus the average foreign tax rate a firm faced in 1985.

To determine the international distribution of patenting, the 422 sample firms were matched to the database of U.S. patents created by the NBER and Case-Western Reserve University.\textsuperscript{20} The NBER/CWRU database contains all patents granted by the U.S. government between 1963 and 1996. This database, based on the public patent records, identifies for every patent the inventors, the geographic location of the inventors, and a corporate “assignee” (if any)

\textsuperscript{20} For more information on this database, see the description in Trajtenberg, Jaffe and Hall (2000).
to whom the patent right is transferred by the inventor.\textsuperscript{21,22} To utilize these data for the current purpose, it was necessary to identify all U.S. patents that were taken out by the sample firms or their affiliates, as well as the countries in which the patents originated.

The task of identifying the patents of the sample firms is complicated by two problems. First, the patent office does not utilize an external code or identifier that permits patenting assignees to be linked electronically to data such as the Compustat. Rather, assignees are indicated by name, and the spelling and punctuation of the names are not completely standardized, e.g., there may be patent records for “IBM” and others for “I.B.M.” Secondly, and more fundamentally, companies choose the corporate entity to which the patent will be assigned, and this could be a subsidiary or an affiliated company rather than the parent company. As described further in Hall, Jaffe and Trajtenberg (2000), the NBER/CWRU database contains a match between the corporate assignees in the patent office data and Compustat firms; the match attempts to deal with both of these problems. First, spelling and punctuation variations were standardized by removing all spaces, punctuation, generic words (e.g. “Inc.” and “Co.”) and searching for apparent multiple versions of the same entities based on these compressed names. All potential matches of this sort were checked by hand to ensure that they were real. Second, approximately 30,000 subsidiaries and affiliates of the Compustat universe as indicated in Who Owns Whom Directory of Corporate Affiliations in 1989 were matched to the patent database to

\textsuperscript{21} Patents must be taken out by the individual or individuals who created the invention. About three-fourths of all patents are “assigned” at the time of the patent application to an institution, typically the inventors’ employer.  
\textsuperscript{22} The NBER/CWRU database contains additional information not used in this paper, including a technological classification of the patent and information about citations between patents. See Jaffe and Trajtenberg (1999) and Trajtenberg, Jaffe and Hall (2000).
identify patents taken out by these affiliates, and these affiliated patents were assigned to the
parent companies for the purpose of this paper.

The geographic location of the patent is based on the location of the first inventor listed
on the patent.\textsuperscript{23} The inventor locations in the patent data are domestic residences (not
citizenships or nationalities) of inventors as indicated on patent applications. Hence, it is
reasonable to expect that a patent based on an invention from an IBM laboratory in Japan would
be coded as a “Japanese” patent. The patent might be assigned to IBM, Inc. or it might be
assigned to an affiliate or subsidiary organized in Japan. Either way, in principle, it would be
treated as if it were an IBM patent, so long as the \textit{Who Owns Whom} directory includes the
ownership link. Certainly, it is possible for some subsidiaries and affiliates to be omitted in this
classification, which would mean that the foreign patent counts of their parent firms are
systematically biased downward. Further, to the extent that the creation of such foreign affiliates
or the assignment of patents to them has changed over time, the change in foreign patents for
these firms might be systematically biased. There is no obvious reason, however, why such an
undercount of foreign patents would be correlated with the other variables of interest.

For purposes of estimation the data are combined to form two observations for each firm,
one corresponding to the 1983-1986 period, and a second corresponding to the 1988-1991 period.
Foreign and domestic patents are summed over the four years that constitute each period. The
specification of (12) that is then estimated is one in which the dependent variable is the

\textsuperscript{23} Jaffe, Henderson and Trajtenberg (1993) investigated the extent of geographic dispersion among the inventors on
a given patent. They found that all inventors on a given patent listed the same country of residence on 98\% of all
patents (including those with a single inventor).
difference between the number of foreign patents taken during the 1988-1991 period and the number taken during the 1983-1986 period. Similarly, the change in domestic patents variable that appears on the right side of (12) equals the difference between the number of domestic patents taken during the 1988-1991 period and the number taken during the 1983-1986 period.

Table 2 presents country-level information on foreign patents by firms in the sample, along with other indicators of activity by the foreign affiliates of American multinational firms. Foreign patenting is concentrated in a relatively small number of technologically advanced countries, which is not surprising; nor is it surprising that R&D spending by the foreign affiliates of American multinational firms is concentrated in roughly the same countries. Indeed, the five foreign countries with the most patents over the period 1988-1991 attributed to resident inventors (the United Kingdom, Japan, Germany, Canada, and France) lead all others in R&D spending by American multinational firms in 1989. To be sure, there is important variation between countries, and most importantly, the vast majority of American patents taken out by sample firms have inventors that are residents of the United States. But the foreign data presented in Table 2 serves to confirm the reasonableness of the patent attribution method on which is based the empirical work that follows.

4. Results.

As a prelude to estimating the model implied by Equation (12), the regressions reported in Table 3 look simply at the firm-level relationship between R&D and patents as it is evident in the data. Columns one and two of Table 3 present estimates in which the dependent variable is
the log of total (worldwide) firm patents over the 1982-1985 period, and the independent
variables include the log of R&D spending in 1986 and log of total firm assets in 1986. The
sample analyzed in these regressions is limited to firms with nonzero patents over 1982-1985,
and those with positive R&D spending and total assets in 1986.

Consistent with other work, the results indicate a strong correlation between patenting
and R&D activity, one that is not simply a function of firm size (as measured by assets). The
regression of log of patents on log R&D (reported in column one) shows slightly less than
constant returns of patents to R&D, although this result is somewhat sensitive to how the
observations with no patents are treated. When log of total assets is added to the regression, as it
is in the regression reported in column two, log assets absorbs part of the explanatory power of
log R&D, but the results continue to imply a patent production function with approximately
constant returns to scale. Columns three and four of Table 3 report regressions using a larger
sample of firms that includes those with no patents over the 1982-1985 period. The dependent
variable in these regressions is now the log of one plus patents, and the right-hand side variables
now include a dummy variable that takes the value one if a firm has nonzero patents over this
time period. The results reported in columns three and four are qualitatively similar to those
reported in columns one and two, in that there is a strong positive relationship between patents
and R&D spending that exhibits decreasing returns.

The consistency of the firm-level patent data with country and firm characteristics (as
evidenced in Tables 2 and 3) offers the prospect of informative estimation of variants of (12)
using these data. Table 4 presents means and standard deviations of the regression variables, and the initial regression results are presented in Table 5. The specification estimated in these regressions is:

\[
P^*_it - P^*_i{t-1} = \exists_1 (P_it - P_{i{t-1}}) + \exists_2 \forall_it + \exists_3 8_it + \exists_4 X_it + \epsilon_it,
\]

\[
8_it / [(1-\alpha_it\tau_t)/(1-\beta_it\tau_t)] - [(1-\alpha_{i{t-1}}\tau_{t-1})/(1-\beta_{i{t-1}}\tau_{t-1})].
\]

Comparing (13) to (12), it follows that the regression coefficients can be interpreted as \(\exists_1 = (c^*/c)\), \(\exists_2\) equals the product of \((c^*/c)\) and a linearization of the \(f(A)\) function, and \(\exists_3\) captures a different linearization of the \(f^*(A)\) function. The reason that the first difference of the \(f(A)\) function may be represented in (13) simply by \(\forall_it\) is that all firms were entitled to deduct their full R&D expenses in the period before 1986, and all faced the same statutory taxes after 1986, so this term differs between firms only in \(\forall_it\). The variable \(X_it\) represents firm-specific characteristics (including a constant term).

Column one of Table 5 reports estimates of (13) without including firm-specific characteristics (other than constants). The estimated coefficients are consistent with the evidence reported in other tables and with a generally complementary relationship between domestic and foreign innovative activity. The estimated value of \(\exists_1\) is approximately 0.06, which means that shocks to domestic patenting translate rather little into changes in foreign patents – reflecting the much larger share of U.S. inventors than foreign inventors among the patents taken out by

---

24 See, e.g., Bound et al. (1984).
American firms. The estimated value of $\exists_2$ is positive but not significant; though this is not of great consequence, since $\forall_{it}$ is included in (13) merely in order to control for changes in domestic patenting due to tax changes rather than firm-specific shocks.

The negative and significant estimated value of $\exists_3$ implies that greater deductibility of R&D expenses in 1991 is associated with increased foreign patenting. Specifically, lower tax costs of performing R&D in the United States for use abroad are associated with greater foreign patents in the second (1988-1991) period relative to the first (1983-1986). In order to interpret the magnitude of the estimated value of $\exists_3$, it is important to bear in mind the construction of the R&D tax incentive variable, and specifically, the use of average foreign tax rates in place of $\exists_{it}$. Since a ten percent difference in average foreign tax rates is generally sufficient to move firms between excess and deficit foreign tax credit status, it follows that the estimated value of $\exists_3$ (without this correction) overstates by a factor of ten the impact of changes in the tax treatment of royalties. The estimated coefficient of $-30.8$ in column one therefore implies that changing the domestic taxation of foreign-source royalties from taxable to not taxable, would, for a firm with the mean value of $\alpha_{it} = 0.88$, be responsible for 1.1 additional foreign patents over the 1988-1991 period. Given the sample mean value of 5.4 foreign patents over the 1983-1986 period, this estimate implies that the cross elasticity of foreign patents with respect to the after-tax cost of domestic R&D directed at foreign markets is between 0.2 and 0.4. This estimate is of the same order of magnitude, though of a different sign, as estimates of international R&D and royalty substitutability reported by Hines (1995). These behavioral elasticities are considerably smaller than an own-price R&D demand elasticity of unity or greater, as reported by Hall (1993) and

Column two of Table 5 presents estimated coefficients from a regression that adds as an independent variable the 1991 ratio of foreign to total sales. The purpose of this somewhat ad hoc addition is to control for a form of unobserved heterogeneity, in which firms that differ in their degrees of multinationality also differ in other unobserved dimensions that affect changes in foreign patenting. Firms with greater foreign sales in 1991 show faster growth of foreign patenting, though in other ways the results presented in column two differ little from those presented in column one. The estimated tax effects in the column two regression are somewhat smaller than those in the first specification of the equation, but remain significant and of the same sign.

Table 6 reports results from a different specification of (12):

\[
\begin{align*}
(14) \quad P_{it}^* - P_{it-1}^* &= \exists_1 (P_{it} - P_{it-1}) + \exists_2 P_{it-1}^* + \exists_3 P_{it-1}^* 8_{it} + \exists_4 X_{it} + u_{it}, \\
&= 8_{it} / [(1-\alpha_{it}\tau_t)/(1-\beta_{it}\tau_t)] - [(1-\alpha_{it-1}\tau_{t-1})/(1-\beta_{it-1}\tau_{t-1})].
\end{align*}
\]

The specification (14) is a close variant of (13), with the difference that the independent variables are now interacted with numbers of foreign patents over 1983-1986. The specification in (14) is intended to provide a natural scaling for the price-type variables that appear on the right side of (12).

The results reported in Table 6 are quite consistent with those reported in Table 5. Firms with rapidly growing domestic patenting exhibit faster than average growth of foreign patenting.
Of particular interest is the estimated –14.6 value of $\exists_3$ in the regression reported in column one. Again taking a ten percent change in the average foreign tax rate to be sufficient to change foreign tax credit status, it follows that the –14.6 coefficient implies roughly a 0.5 cross-price elasticity of foreign R&D with respect to the cost of domestic R&D directed at foreign markets. As is evident from the results reported in columns two through four of Table 6, minor specification changes affect this estimated behavioral elasticity very little.

5. Conclusions.

This study considers the effect of changes in the after-tax cost of R&D on subsequent patenting by American firms in the United States and abroad. The purpose is to estimate the impact of tax policy on the location of successful inventive activity. Tax policy affects patent location by influencing the location of R&D and therefore the likelihood of producing patentable inventions. Recent U.S. tax changes affect some American firms more strongly than others, making it possible to estimate the effect of tax policies on innovation by comparing reactions to the changes.

The results indicate that firms for which after-tax costs of performing R&D in the United States for use abroad rose most rapidly after 1986 exhibit the slowest growth of foreign patenting in subsequent years. Estimated cross-price elasticities of foreign patenting with respect to the cost of domestic R&D directed at foreign markets vary between 0.2 and 0.5. This suggests not only that tax incentives influence subsequent patenting patterns, but that foreign and domestic innovative activities are complements at the firm level. While this is an intuitively appealing
finding, it is inconsistent with available evidence of the international substitutability of R&D activity as measured at the aggregate level. This raises the interesting possibility that domestic and foreign innovation, while complements for individual firms, become substitutes between economies due to induced effects on the composition of industry or for other reasons.

Note to Table 2: Columns one and two report total numbers of U.S. patents granted to the 378 American firms in the sample and assigned to inventors located in designated countries. Column 3 reports aggregate dollar values (in $ millions) of the local property, plant, and equipment of majority owned nonbank affiliates of nonbank American parent firms in 1989. Column 4 reports aggregate sales (in $ millions) of majority owned nonbank affiliates of nonbank American parent firms in 1989. Column 5 reports aggregate R&D expenditures (in $ millions) on behalf of majority owned nonbank affiliates of nonbank American parent firms in 1989. The “d” entry in column 5 indicates that data are suppressed to protect the identity of individual survey respondents, while the “*” entry indicates R&D spending of less than $500,000. Data reported in columns 3-5 are drawn from United States Department of Commerce (1992).

Note to Table 3: The table reports estimated coefficients from OLS regressions. The dependent variable in the regressions reported in the first two columns is the log of the number of new patents (domestic plus foreign) taken out between 1982 and 1985. Observations are included in the samples analyzed in these regressions only if they have nonzero and nonmissing patent and R&D data. The dependent variable in the regressions reported in columns three and four is the log of one plus the number of new patents (domestic plus foreign) taken out between 1982 and 1985. Observations are included in the samples analyzed in these regressions only if they have nonzero and nonmissing R&D data. “ln(R&D, 1986)” is the log of total R&D expenditures in 1986. “Patents dummy” is a dummy variable that equals one if a firm took out nonzero patents between 1982 and 1985, and equals zero otherwise. “ln(Assets, 1986)” is the log of total firm assets in 1986. number of new domestic patents taken out between 1988 and 1992. Heteroskedasticity-consistent standard errors are in parentheses.

Note to Table 5: The table reports estimated coefficients from OLS regressions. The dependent variable is the difference between the number of new foreign patents taken out during 1988-1991 (inclusive) and the number taken out during 1983-1986 (inclusive). “Change in domestic patents” is the difference between the number of new domestic patents taken out during 1988-1991 (inclusive) and the number taken out during 1983-1986 (inclusive). “R&D expense deductibility, 1991” equals the fraction of domestic R&D expenses that firms can deduct against their domestic tax liabilities in 1991. “Change in R&D tax incentives (foreign)” equals the change in the required cost of capital for a $1 investment in domestic R&D intended to enhance foreign profitability. “Percent foreign sales, 1991” equals the fraction of a firm’s sales that are foreign in 1991. Heteroskedasticity-consistent standard errors are in parentheses.
