INHOMOGENEOUS DIOPHANTINE APPROXIMATION
FOR GENERIC HOMOGENEOUS FUNCTIONS

DMITRY KLEINBOCK AND MISHEL SKENDERI

Abstract. The present paper is a sequel to [Monatsh. Math. 194 (2021), 523–554] in which results of that paper are generalized so that they hold in the setting of inhomogeneous Diophantine approximation. Given any integers \( n \geq 2 \) and \( \ell \geq 1 \), any \( \xi = (\xi_1, \ldots, \xi_{\ell}) \in \mathbb{R}^\ell \), and any homogeneous function \( f = (f_1, \ldots, f_{\ell}) : \mathbb{R}^n \to \mathbb{R}^\ell \) that satisfies a certain nonsingularity assumption, we obtain a biconditional criterion on the approximating function \( \psi = (\psi_1, \ldots, \psi_{\ell}) : \mathbb{R}_{\geq 0} \to (\mathbb{R}_{>0})^\ell \) for a generic element in the \( G \)-orbit of \( f \) to be (respectively, not to be) \( \psi \)-approximable at \( \xi \): that is, for there to exist infinitely many (respectively, only finitely many) \( v \in \mathbb{Z}^n \) such that \(|\xi_j - (f_j \circ g)(v)| \leq \psi_j(\|v\|)\) for each \( j \in \{1, \ldots, \ell\} \). In this setting, we also obtain a sufficient condition for uniform approximation. We also consider some examples of \( f \) that do not satisfy our nonsingularity assumptions and prove similar results for these examples. Here, \( G \) can be any closed subgroup of \( \text{ASL}_n(\mathbb{R}) \) (such as \( \text{ASL}_n(\mathbb{R}) \) itself or \( \text{SL}_n(\mathbb{R}) \)) that satisfies certain axioms introduced by the authors in the aforementioned previous paper.

1. Introduction

Let \( f \) be an indefinite and nondegenerate quadratic form in \( n \geq 3 \) real variables that is not a real multiple of a quadratic form with rational coefficients. The Oppenheim–Davenport Conjecture, resolved affirmatively by G. A. Margulis in [16], states that every real number is an accumulation point of \( f(\mathbb{Z}^n) \): that is to say, for any \( \xi \in \mathbb{R} \) and any \( \varepsilon \in \mathbb{R}_{>0} \),

(1.1) there exist infinitely many \( v \in \mathbb{Z}^n \) for which \(|f(v) - \xi| \leq \varepsilon\).

The rich history of the Oppenheim–Davenport conjecture and its seminal resolution by Margulis, among various other related topics, are extensively discussed in Margulis’s survey [17]. The influence of Margulis’s theorem and related problems continues unabated to this day. As of a few years ago, there has been a great increase of activity in proving effective variants of Margulis’s theorem for generic quadratic forms and other homogeneous polynomials: for instance, one often considers the \( \text{SL}_n(\mathbb{R}) \)-orbit (under the natural action) of a real homogeneous polynomial in \( n \) real variables; one then has a natural notion of measure class (and thus measure-theoretic genericity) for this orbit. Let us briefly recall some recent results that exemplify this circle of problems.

For any \( \beta \in \mathbb{R}_{\geq 1} \) and any \( (p, q) \in (\mathbb{Z}_{\geq 1})^2 \) with \( p + q = n \geq 3 \), let \( F_{p,q,\beta} : \mathbb{R}^n \to \mathbb{R} \) be given by

(1.2) \[ F_{p,q,\beta}(x) := \sum_{j=1}^{p} |x_j|^\beta - \sum_{k=p+1}^{n} |x_k|^\beta. \]
Generalizing earlier results of Ghosh–Gorodnik–Nevo \cite{8} and Athreya–Margulis \cite{1}, Kelmer–Yu proved the following theorem.

**Theorem 1.1** (\cite{13} Corollary 2). Let $\beta \in 2(\mathbb{Z}_{\geq 1})$, let $n \in \mathbb{Z}_{>\beta}$, and let $p$ and $q$ be elements of $\mathbb{Z}_{\geq 1}$ for which $p + q = n$. Let $s \in (0, n - \beta) \subset \mathbb{R}$. Let $\xi \in \mathbb{R}$. Then for Haar-almost every $g \in \text{SL}_n(\mathbb{R})$ the following holds: for each sufficiently large $T \in \mathbb{R}_{>0}$ there exists $v \in \mathbb{Z}^n$ with
\[ 0 < \|v\| \leq T \quad \text{and} \quad |\xi + F_{p,q,\beta}(gv)| \leq T^{-s}, \]
where $\| \cdot \|$ is a certain norm on $\mathbb{R}^n$.

The proof of Ghosh–Gorodnik–Nevo made use of representation theory and effective mean ergodic theorems, while those of Athreya–Margulis and then Kelmer–Yu employed comparatively elementary means (namely, first and second moment formulae for the Siegel transform in the geometry of numbers).

For other results of a similar nature, see \cite{2,5,7,9,11,14,15}. The authors previously studied problems of this sort in \cite{14}; however, the work in \cite{14} was limited to *homogeneous* approximation, which corresponds to the special case $\xi = 0$ in the context of \cite{14}. The purpose of the present paper is to establish *inhomogeneous* analogues of the results of \cite{14}. In order both to recall the results of \cite{14} and to present the results of the present paper, we proceed to establish some notation and definitions; much of the notation and many of the definitions that follow were first established in \cite{14} and are recalled here for the convenience of the reader.

Now and hereafter, we shall denote by $n$ an arbitrary element of $\mathbb{Z}_{\geq 2}$ and by $\ell$ an arbitrary element of $\mathbb{Z}_{\geq 1}$. Elements of $\mathbb{R}^n$ and of $\mathbb{R}^\ell$ shall always be regarded as column vectors, even though they may be written as row vectors for notational convenience. If $k \in \mathbb{Z}_{\geq 1}$ is arbitrary and $E$ is any subset of $\mathbb{R}^k$, then we define $E_{\neq 0} := E \setminus \{0_{\mathbb{R}^k}\}$. We say that an arbitrary point $v = (v_1, \ldots, v_n) \in \mathbb{Z}^n$ is *primitive* if $\gcd(v_1, \ldots, v_n) = 1$. We let $\mathbb{Z}_{p_0}^n$ denote the set of all primitive points of $\mathbb{Z}^n$. We shall always denote the usual Lebesgue measure on any Euclidean space by $m$. Throughout this paper, we shall use the Vinogradov notation $\ll$ and use $\asymp$ to denote that both $\ll$ and $\gg$ hold; we shall attach subscripts to the symbols $\ll$ and $\asymp$ to indicate the parameters, if any, on which the implicit constants depend.

**Definition 1.2** (\cite{14} Definition 1.1]). We define a non-strict partial order $\ll$ on $\mathbb{R}^\ell$ as follows. For any $x = (x_1, \ldots, x_\ell) \in \mathbb{R}^\ell$ and any $y = (y_1, \ldots, y_\ell) \in \mathbb{R}^\ell$, we write $x \ll y$ if and only if for each $j \in \{1, \ldots, \ell\}$, we have $x_j \leq y_j$. (Equivalently, we write $x \ll y$ if and only if $(y - x) \in (\mathbb{R}_{\geq 0})^\ell$.)

**Definition 1.3** (see \cite{14} Definitions 1.2, 3.3, 3.6, and 3.7]). Let
\[ f = (f_1, \ldots, f_\ell) : \mathbb{R}^n \to \mathbb{R}^\ell \quad \text{and} \quad \psi = (\psi_1, \ldots, \psi_\ell) : \mathbb{R}_{\geq 0} \to (\mathbb{R}_{>0})^\ell \]
be given, let $\nu$ be an arbitrary norm on $\mathbb{R}^n$, and let $\mathcal{P}$ be an arbitrary subset of $\mathbb{Z}^n$.

- We abuse notation and write $|f|$ to denote the function $(|f_1|, \ldots, |f_\ell|) : \mathbb{R}^n \to \mathbb{R}^\ell$.
- We define $Z(f) := f^{-1}(0_{\mathbb{R}^\ell}) \setminus \{0_{\mathbb{R}^n}\}$.
- We define $A_{f,\psi,\nu} := \{x \in \mathbb{R}^n : |f(x)| \ll \nu(\psi(x))\}$.
- For any $T \in \mathbb{R}_{>0}$ and any $\epsilon \in (\mathbb{R}_{>0})^\ell$, we define
\[ B_{f,\epsilon,\psi,T} := \{x \in \mathbb{R}^n : |f(x)| \ll \epsilon \quad \text{and} \quad \nu(x) \leq T\}. \]

- We say that $f$ is $(\psi, \nu, \mathcal{P})$-approximable if $A_{f,\psi,\nu} \cap \mathcal{P}$ has infinite cardinality.
- We say that $f$ is uniformly $(\psi, \nu, \mathcal{P})$-approximable if $B_{f,\psi(T),\nu,T} \cap \mathcal{P} \neq \emptyset$ for each sufficiently large $T \in \mathbb{R}_{>0}$.
- We say that $f$ is homogeneous if it is Borel measurable and there exists some $d = d(f) = (d_1, \ldots, d_\ell) \in (\mathbb{R}_{>0})^\ell$ such that for each $t \in \mathbb{R}_{>0}$, each $j \in \{1, \ldots, \ell\}$, and each $x \in \mathbb{R}^n$ we have $f_j(tx) = t^{d_j}f_j(x)$. We refer to $d = d(f)$ as the degree of $f$.
- We say that $\psi$ is regular if it is Borel measurable and there exist real numbers $a = a(\psi) \in \mathbb{R}_{>1}$ and $b = b(\psi) \in \mathbb{R}_{>0}$ such that for each $z \in \mathbb{R}_{>0}$ one has $b\psi(z) \ll \psi(az)$.
- We say that $\psi$ is nonincreasing if each component function of $\psi$ is nonincreasing in the usual sense.

**Definition 1.4.** For any function $f : \mathbb{R}^n \to \mathbb{R}^\ell$ and any $\xi \in \mathbb{R}^\ell$, define $\xi f : \mathbb{R}^n \to \mathbb{R}^\ell$ to be the function given by $\xi f(x) := -\xi + f(x)$.

\footnote{This terminology is slightly abusive because $d = d(f)$ is unique if and only if each component of $f$ is nonzero.}
Definition 1.5. For any \( s \in \mathbb{R}_{>0} \) and any \( \varepsilon \in \mathbb{R}_{\geq 0} \), let \( \varphi_{s,\varepsilon} : \mathbb{R}_{>0} \to \mathbb{R}_{>0} \) be any regular and nonincreasing function such that for every sufficiently large \( t \in \mathbb{R}_{>1} \) we have \( \varphi_{s,\varepsilon}(t) = t^{-s}(\log t)^\varepsilon \).

Using our newly introduced terminology, we may now restate Theorem 1.1 as follows.

Theorem 1.1' (\cite{[13]} Corollary 2). Let \( \beta \in 2(\mathbb{Z}_{\geq 1}) \), let \( n \in \mathbb{Z}_{>\beta} \), and let \( p \) and \( q \) be elements of \( \mathbb{Z}_{>1} \), for which \( p + q = n \). Let \( s \in (0, n - \beta) \subset \mathbb{R} \). Let \( \xi \in \mathbb{R} \). Let \( \| \cdot \| \) be a certain norm on \( \mathbb{R}^n \). Set \( f := F_{p,q,\beta} \). Then the following hold.

(i) The function \( (\xi f) \circ g \) is \( (\varphi_{s,0}, \| \cdot \|, \mathbb{Z}_n) \)-approximable for Haar-almost every \( g \in \mathrm{SL}_n(\mathbb{R}) \).

(ii) The function \( (\xi f) \circ g \) is uniformly \( (\varphi_{s,0}, \| \cdot \|, \mathbb{Z}_n) \)-approximable for Haar-almost every \( g \in \mathrm{SL}_n(\mathbb{R}) \).

We now proceed to state certain results that will be formulated and proved in greater generality in \cite{[3]}. Before we state the first result, let us recall an elementary notion from differential topology.

Definition 1.6. Let \( M \) and \( N \) be \( \mathcal{C}^1 \) manifolds that are Hausdorff, second-countable, and without boundary. Let \( U \) be an open subset of \( M \). Let \( f : M \to N \) be a function, and suppose that \( f \) is continuously differentiable on \( U \). Let \( x \in U \) be given. We say that \( x \) is a regular point of \( f \) if the map \( D_x f : T_x M \to T_{f(x)} N \) is surjective.

Theorem 1.7. Let \( \psi = (\psi_1, \ldots, \psi_{\ell}) : \mathbb{R}_{\geq 0} \to (\mathbb{R}_{>0})^\ell \) be regular and nonincreasing. Let \( f = (f_1, \ldots, f_{\ell}) : \mathbb{R}^n \to \mathbb{R}^\ell \) be homogeneous of degree \( d = d(f) = (d_1, \ldots, d_{\ell}) \in (\mathbb{R}_{>0})^\ell \). Suppose further that \( f \) is continuously differentiable on \( \mathbb{R}^n_{\neq 0} \), that \( Z(f) \neq \emptyset \), and that

\[
\text{(1.3) each element of } Z(f) \text{ is a regular point of } f.
\]

Let \( \nu \) be an arbitrary norm on \( \mathbb{R}^n \). Let \( \xi \in \mathbb{R}^\ell \). Set \( d := \sum_{j=1}^{\ell} d_j \). Then the following hold.

(i) If \( \int_1^\infty t^{-n(d+1)} \left( \prod_{j=1}^{\ell} \psi_j(t) \right) \, dt \) is finite (respectively, infinite), then \( (\xi f) \circ g \) is \( (\psi, \nu, \mathbb{Z}_n) \)-approximable for Haar-almost no (respectively, almost every) \( g \in \mathrm{SL}_n(\mathbb{R}) \).

(ii) Suppose that \( d < n \) and that the infinite series \( \sum_{k=1}^{\infty} \frac{2^{k(n-d)}}{\prod_{j=1}^{\ell} \psi_j \left( 2^k \right)} \) converges. Then \( (\xi f) \circ g \) is uniformly \( (\psi, \nu, \mathbb{Z}_n) \)-approximable for Haar-almost every \( g \in \mathrm{SL}_n(\mathbb{R}) \).

Remark 1.8. Notice that no component of \( f \) in the above theorem is required to be a polynomial. Notice also that neither the integral criterion in (i) nor the summatory condition in (ii) features any dependence on \( \xi \in \mathbb{R}^\ell \).

Remark 1.9. It will follow from a more general result in \cite{[3]} that the preceding theorem remains true if one replaces

- each instance of \( \mathbb{Z}_n \) by \( \mathbb{Z}_p^2 \);
- each instance of \( \mathbb{Z}_p^2 \) by \( \mathbb{Z}^n \) and each instance of \( \mathrm{SL}_n(\mathbb{R}) \) by \( \mathrm{ASL}_n(\mathbb{R}) \). Here, \( \mathrm{ASL}(\mathbb{R}) := \mathrm{SL}_n(\mathbb{R}) \times \mathbb{R}^n \), the group of affine isomorphisms of \( \mathbb{R}^n \) that preserve both volume and orientation.

Remark 1.10. Notice that statement (ii) of Theorem 1.7 easily implies Theorem 1.1 in fact, we may readily generalize Theorem 1.1 as follows. Let \( \beta, p, q, n = p + q \), and \( F_{p,q,\beta} : \mathbb{R}^n \to \mathbb{R} \) be as in \cite{[12]}. Suppose further \( 1 < \beta < n \). Since \( \beta > 1 \), the function \( F_{p,q,\beta} \) is continuously differentiable on \( \mathbb{R}^n \). Since \( p \geq 1 \) and \( q \geq 1 \), we have \( Z(F_{p,q,\beta}) \neq \emptyset \). It is also easy to verify that each element of \( \mathbb{R}^p_{\neq 0} \) is a regular point of \( F_{p,q,\beta} \). The hypotheses of Theorem 1.7 are thus satisfied when \( \ell = 1, d = 1, \beta = 1 \), and \( f = F_{p,q,\beta} \). Now let \( \xi \in \mathbb{R} \) be arbitrary, let \( \nu \) be an arbitrary norm on \( \mathbb{R}^n \), and set \( f = F_{p,q,\beta} \) to simplify notation. The following then hold.

- The function \( (\xi f) \circ g \) is \( (\varphi_{n,0}, \nu, \mathbb{Z}_p^2) \)-approximable for Haar-almost every \( g \in \mathrm{SL}_n(\mathbb{R}) \). This generalizes (i) of Theorem 1.1' to include the case of the critical exponent \( s = n - \beta \).

\footnote{Statement (i) is a straightforward corollary of statement (ii).}
The function \((\xi f) \circ g\) is uniformly \((\varphi_{n-\beta,\epsilon},\nu,\mathbb{Z}_p^n)\)-approximable for every \(\epsilon \in \mathbb{R}_{>1}\) and Haar-almost every \(g \in \text{SL}_n(\mathbb{R})\). This generalizes (ii) of Theorem 1.1. In fact, one can generalize (ii) of Theorem 1.1 even further by suitably modifying the definition of \(\varphi_{n-\beta,\epsilon}\) to include an arbitrary and finite number of iterated logarithms.

**Remark 1.11.** Our general framework also allows for easy consideration of vector-valued examples of \(f\). For instance, let \(f_1 = F_{p,q,\beta} : \mathbb{R}^n \to \mathbb{R}\) as in Remark 1.10 and let \(f_2 : \mathbb{R}^n \to \mathbb{R}\) be an \(\mathbb{R}\)-linear transformation. (These functions may remind the reader of the setting in the papers \([3,6,12]\).) Then \(f := (f_1, f_2) : \mathbb{R}^n \to \mathbb{R}^2\) satisfies the hypotheses of Theorem 1.1 if and only if the intersection \(Z(f_1) \cap Z(f_2)\) is nonempty and transverse. One thereby obtains a criterion for the asymptotic approximability of and a sufficient condition for the uniform approximability of almost every element in the \(\text{SL}_n(\mathbb{R})\)-orbit of \(\xi f\).

We are also able to obtain results akin to Theorem 1.7 in certain special cases wherein the nonsingularity condition (1.3) does not hold. In Theorem 1.7 and in all the aforementioned examples, the integral and summatory conditions obtained were all independent of \(\xi\). Let \(n\) for the uniform approximability of almost every element in the \(\text{SL}_n(\mathbb{R})\)-orbit of \(\xi f\).

**Theorem 1.12.** Let \(\psi : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}\) be regular and nonincreasing. Let \(\omega \in \mathbb{R}_{>0}\) be arbitrary. Let \(f : \mathbb{R}^n \to \mathbb{R}\) be given by \(f(x) := (\prod_{i=1}^n |x_i|)^\omega\). Let \(\nu\) be an arbitrary norm on \(\mathbb{R}^n\). Let \(\xi \in \mathbb{R}_{\geq 0}\). Then the following hold.

(i) If

\[
\int_1^{\infty} \frac{\psi(t)^{1/\omega}}{t} (\log t)^{n-2} \, dt \quad \text{if } \xi = 0
\]

\[
\int_1^{\infty} \frac{\psi(t)^{1/\omega}}{t} (\log t)^{n-2} \, dt \quad \text{if } \xi > 0
\]

is finite respectively, infinite), then \((\xi f) \circ g\) is \((\psi, \nu, \mathbb{Z}_p^n)\)-approximable for Haar-almost no (respectively, almost every) \(g \in \text{SL}_n(\mathbb{R})\).

(ii) If the infinite series

\[
\sum_{k=1}^{\infty} \left[k^{n-1} \psi(2^k)^{1/\omega}\right]^{-1} \quad \text{if } \xi = 0
\]

\[
\sum_{k=1}^{\infty} \left[k^{n-1} \psi(2^k)^{1/\omega}\right]^{-1} \quad \text{if } \xi > 0
\]

converges, then \((\xi f) \circ g\) is uniformly \((\psi, \nu, \mathbb{Z}_p^n)\)-approximable for Haar-almost every \(g \in \text{SL}_n(\mathbb{R})\).

**Theorem 1.13.** Let \(\psi : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}\) be regular and nonincreasing. Let \(p \in \{1, \ldots, n-1\}\) and \(z = (z_1, \ldots, z_p) \in (\mathbb{R}_{>0})^p\) be given. Let \(f : \mathbb{R}^n \to \mathbb{R}\) be given by

\[
f(x_1, \ldots, x_n) := \max \{|x_i|^{z_i} : 1 \leq i \leq p\}.
\]

Set \(z := \sum_{i=1}^p z_i^{-1}\). Let \(\nu\) be an arbitrary norm on \(\mathbb{R}^n\). Let \(\xi \in \mathbb{R}_{\geq 0}\). Then the following hold.

(i) If

\[
\int_1^{\infty} \psi(t) t^{n-(p+1)} \, dt \quad \text{if } \xi = 0
\]

\[
\int_1^{\infty} \psi(t) t^{n-(p+1)} \, dt \quad \text{if } \xi > 0
\]

is finite respectively, infinite), then \((\xi f) \circ g\) is \((\psi, \nu, \mathbb{Z}_p^n)\)-approximable for Haar-almost no (respectively, almost every) \(g \in \text{SL}_n(\mathbb{R})\).

(ii) If the infinite series

\[
\sum_{k=1}^{\infty} \left[2^{(n-p)k} \psi(2^k)^z\right]^{-1} \quad \text{if } \xi = 0
\]

\[
\sum_{k=1}^{\infty} \left[2^{(n-p)k} \psi(2^k)^z\right]^{-1} \quad \text{if } \xi > 0
\]
We say that \(G\) is of Siegel type if there exists a constant \(c \in \mathbb{R}_{>0}\) such that for any bounded and compactly supported Borel measurable function \(f : \mathbb{R}^n \to \mathbb{R}_{\geq 0}\) we have
\[
\int_X \hat{f}^P \, d\mu_X = c \int_{\mathbb{R}^n} f \, dm.
\]

We may identify \(X\) with \(\mathbb{R}^n\) in the usual manner: for any \((h, z) \in \text{ASL}_n(\mathbb{R})\) and any \(x \in \mathbb{R}^n\), we have \((h, z)x = z + hx\). Let \(G\) be a closed subgroup of \(\text{ASL}_n(\mathbb{R})\) and let \(\Gamma\) denote the subgroup of \(G\) given by
\[
(2.1) \quad \Gamma := \{g \in G : g\mathbb{Z}^n = \mathbb{Z}^n\}.
\]

Now and hereafter, we assume that \(\Gamma\) is a lattice in \(G\). (Each particular example of a closed subgroup \(G \leq \text{ASL}_n(\mathbb{R})\) that we shall consider will indeed satisfy this condition.) Set \(X := G/\Gamma\). We let \(\mu_G\) denote the Haar measure on the unimodular group \(G\) that is normalized so that \(\text{vol}(G/\Gamma) = 1\). Then let \(\mu_X\) denote the unique \(G\)-invariant Radon probability measure on \(X\).

We may identify \(X\) and \(\{g\mathbb{Z}^n : g \in G\}\) via the bijection \(g \Gamma \mapsto g\mathbb{Z}^n\); we then equip \(\{g\mathbb{Z}^n : g \in G\}\) with the quotient topology of \(X\) by declaring the aforementioned bijection to be a homeomorphism. Now let \(\mathcal{P}\) be any \(\Gamma\)-invariant subset of \(\mathbb{Z}^n\). Given any \(\Lambda \in X\), fix any \(g \in G\) for which \(\Lambda = g\mathbb{Z}^n\); then define \(\Lambda_\mathcal{P} := g\mathcal{P}\). Then \(\Lambda_\mathcal{P}\) is well-defined because \(\mathcal{P}\) is \(\Gamma\)-invariant. Given any function \(f : \mathbb{R}^n \to \mathbb{R}_{\geq 0}\), we define its \(\mathcal{P}\)-Siegel transform \(\hat{f}^\mathcal{P} : X \to [0, \infty]\) by
\[
\hat{f}^\mathcal{P}(\Lambda) := \sum_{\nu \in \Lambda_\mathcal{P}} f(\nu).
\]

The Siegel and Rogers axioms are as follows.

**Definition 2.1** ([14, Definition 2.1]). Let \(G\) and \(\mathcal{P}\) be as above.

(i) We say that \(G\) is of \(\mathcal{P}\)-Siegel type if there exists a constant \(c = c_\mathcal{P} \in \mathbb{R}_{>0}\) such that for any bounded and compactly supported Borel measurable function \(f : \mathbb{R}^n \to \mathbb{R}_{\geq 0}\) we have
\[
\int_X \hat{f}^\mathcal{P} \, d\mu_X = c \int_{\mathbb{R}^n} f \, dm.
\]

(ii) Let \(r \in \mathbb{R}_{\geq 1}\) be given. We say that \(G\) is of \((\mathcal{P}, r)\)-Rogers type if there exists a constant \(D = D_{\mathcal{P}, r} \in \mathbb{R}_{>0}\) such that for any bounded Borel \(E \subset \mathbb{R}^n\) with \(m(E) > 0\) we have
\[
\left\| \hat{1}_E^\mathcal{P} - \left( \int_X \hat{1}_E^\mathcal{P} \, d\mu_X \right) \hat{1}_X \right\|_{r} \leq D \cdot m(E)^{1/r}.
\]

There are various interesting examples of \((G, \Gamma, \mathcal{P})\) that satisfy both conditions (i) (Siegel) and (ii) (Rogers) of Definition 2.1; see [14, Theorems 2.5, 2.6, and 2.8] and the references therein. These axioms are expedient because they can be used in tandem with the Borel–Cantelli Lemma (for the purpose of uniform approximation) and to prove analogues of W.M. Schmidt’s famous counting result [21, Theorems 1 and 2] (for the purpose of asymptotic approximation). We now recall a result from [14] that records the relevant consequences of the Siegel and Rogers axioms.
Theorem 2.2. [14, Theorem 2.9] Let $G$ be a closed subgroup of $\text{ASL}_n(\mathbb{R})$, let $\Gamma$ be as in [21], and let $\mathcal{P}$ be a $\Gamma$-invariant subset of $\mathbb{Z}^n$. Suppose $G$ is of $\mathcal{P}$-Siegel type with $c = c_\mathcal{P}$. Let $E$ be a Borel measurable subset of $\mathbb{R}^n$.

(i) If $m(E) < \infty$, then $\mu_X\left(\{A \in X : |A \cap E| < \infty\}\right) = 1$.

For the remaining statements of this theorem, suppose in addition to the preceding hypotheses that we are given $r \in \mathbb{R}_{>1}$ for which $G$ is of $(\mathcal{P}, r)$-Rogers type.

(ii) Suppose $m(E) = \infty$. Let $\| \cdot \|$ be a norm on $\mathbb{R}^n$. Then for $\mu_X$-almost every $A \in X$, we have

$$\lim_{t \to \infty} \frac{\# \{x \in (A \cap E) : \|x\| \leq t\}}{cm\left(\{x \in E : \|x\| \leq t\}\right)} = 1.$$  

In particular, $\mu_X\left(\{A \in X : |A \cap E| < \infty\}\right) = 1$.

(iii) Let $\{F_k\}_{k \in \mathbb{Z}_{\geq 1}}$ be a collection of Borel measurable subsets of $\mathbb{R}^n$ with $0 < m(F_k) < \infty$ for each $k \in \mathbb{Z}_{\geq 1}$. Suppose $\sum_{k=1}^{\infty} m(F_k)^{1-r} < \infty$. Then the following holds: for $\mu_X$-almost every $A \in X$, there exists some $k_A \in \mathbb{Z}_{\geq 1}$ such that for each integer $k \geq k_A$, we have $A \cap F_k \neq \emptyset$.

In the authors’ previous paper [14], the assumption on the function $f : \mathbb{R}^n \to \mathbb{R}^\ell$ whose values near zero were being approximated was subhomogeneity; we recall here the definition of this property.

Definition 2.3. Let $f : \mathbb{R}^n \to \mathbb{R}^\ell$. We say that $f$ is subhomogeneous if it is Borel measurable and there exists $\delta = \delta(f) \in (0,1) \subset \mathbb{R}$ and each $x \in \mathbb{R}^n$ we have $|f(tx)| \leq t^\delta|f(x)|$.

In this paper, we wish to prove analogues of [14, Theorems 3.4 and 3.8] in which the subhomogeneous function $f : \mathbb{R}^n \to \mathbb{R}^\ell$ therein is replaced by a function of the form $\xi F$, where $F : \mathbb{R}^n \to \mathbb{R}^\ell$ is some sufficiently well-behaved Borel measurable function and $\xi \in \mathbb{R}^\ell$. The technical starting point for doing so is noting that the subhomogeneity assumption on $f$ in [14] was needed only in order to invoke the conclusions of two important lemmata from [14]; we now recall the statements of these lemmata for the convenience of the reader.

Lemma 2.4. [14, Lemmata 3.1 and 3.5] Let $f : \mathbb{R}^n \to \mathbb{R}^\ell$ be subhomogeneous, and let $\delta = \delta(f) \in (0,1) \subset \mathbb{R}$ as in Definition 2.3. Let $\eta$ and $\nu$ be arbitrary norms on $\mathbb{R}^n$. The following then hold.

(i) Let $s \in \mathbb{R}_{>0}$. Then $m(A_{f,s\psi,\eta}) < \infty$ if and only if $m(A_{f,\psi,\nu}) < \infty$.

(ii) Let $t \in (0,1), T \in \mathbb{R}_{>0}$, and $\xi \in (\mathbb{R}_{>0})^\ell$. Then $tB_{f,\xi,\psi,T} \subseteq B_{f,t\xi,\psi,T}$.

(iii) There exists $C_\xi = C_{\psi,\eta} \in \mathbb{R}_{\geq 1}$ such that for each $C \in \mathbb{R}_{\geq 1}$, each $T \in \mathbb{R}_{>0}$, and each $\xi \in (\mathbb{R}_{>0})^\ell$, we have $B_{f,\xi,\psi,T} \subseteq C B_{f,C^{-\xi}T} \subseteq C B_{f,\xi,\psi,T}$.

In the above lemma shows that the subhomogeneity of $f$ is sufficient to ensure that the volumes of the sets $A_{f,\psi,\nu}$ and $B_{f,\xi,\psi,T}$ are well-behaved under change-of-norms and under scaling of any of the arguments $\xi, T$ by arbitrary elements of $\mathbb{R}_{>0}$. Let us also recall another lemma from [14] to which we shall need to refer.

Lemma 2.5. [14, Lemma 3.2] Let $\psi = (\psi_1, \ldots, \psi_n) : \mathbb{R}_{\geq 0} \to (\mathbb{R}_{>0})^\ell$ be regular and nonincreasing. Then the following holds: for each $c \in \mathbb{R}_{\geq 0}$ there exists $s \in \mathbb{R}_{>0}$ such that for each $x \in [0, c]$ and each $y \in \mathbb{R}_{>c}$, one has $\psi(y - x) \ll s \psi(y)$.

We now formulate definitions that axiomatize (i) of Lemma 2.4 and certain desirable properties furnished by (ii) and (iii) of the same lemma.

Definition 2.6. Let $f : \mathbb{R}^n \to \mathbb{R}^\ell$ be Borel measurable, and let $\psi : \mathbb{R}_{\geq 0} \to (\mathbb{R}_{>0})^\ell$ be regular and nonincreasing. We say that the pair $(f, \psi)$ is asymptotically acceptable if the following holds: for any $s \in \mathbb{R}_{>0}$ and any norms $\nu_1, \nu_2$ on $\mathbb{R}^n$, we have

$$m\left(A_{f,\psi,\nu_1}\right) < \infty \quad \text{if and only if} \quad m\left(A_{f,\psi,\nu_2}\right) < \infty.$$  

Definition 2.7. Let $f : \mathbb{R}^n \to \mathbb{R}^\ell$ and $\psi : \mathbb{R}_{\geq 0} \to (\mathbb{R}_{>0})^\ell$ each be Borel measurable. We say that the pair $(f, \psi)$ is uniformly acceptable if the following holds: for any $s_1, s_2, s_3, s_4 \in \mathbb{R}_{\geq 0}$ and any norms $\nu_1, \nu_2$ on $\mathbb{R}^n$, we have

$$0 < \liminf_{T \to \infty} \frac{m\left(B_{f,s_3\psi(T),\nu_2,s_4T}\right)}{m\left(B_{f,s_1\psi(T),\nu_1,s_2T}\right)} \leq \limsup_{T \to \infty} \frac{m\left(B_{f,s_3\psi(T),\nu_2,s_4T}\right)}{m\left(B_{f,s_1\psi(T),\nu_1,s_2T}\right)} < \infty.$$
Remark 2.8. Note that if \( f : \mathbb{R}^n \rightarrow \mathbb{R}^\ell \) is subhomogeneous and \( \psi : \mathbb{R}_{>0} \rightarrow (\mathbb{R}_{>0})^\ell \) is regular and nonincreasing, then Lemma 2.4 implies that the pair \((f, \psi)\) is both asymptotically acceptable and uniformly acceptable.

Let us now state and prove a lemma that will simplify various proofs in §3 that concern the verification of asymptotic and uniform acceptability.

Lemma 2.9. Let \( f : \mathbb{R}^n \rightarrow \mathbb{R}^\ell \) and \( \psi : \mathbb{R}_{>0} \rightarrow (\mathbb{R}_{>0})^\ell \) each be Borel measurable.

(i) Suppose that \( \psi \) is regular and nonincreasing. Suppose that there exists some norm \( \nu \) on \( \mathbb{R}^n \) such that for any \( s \in \mathbb{R}_{>0} \) we have
\[
m(A_{f, \psi, \nu}) < \infty \quad \text{if and only if} \quad m(A_{f, \psi, \nu}) < \infty.
\]
Then the pair \((f, \psi)\) is asymptotically acceptable.

(ii) Suppose that there exists some norm \( \nu \) on \( \mathbb{R}^n \) such that for any \( s_1, s_2, s_3, s_4 \in \mathbb{R}_{>0} \) we have
\[
0 < \liminf_{T \to \infty} \frac{m(B_{f, s_3 \psi(T), \nu, s_4 T})}{m(B_{f, s_1 \psi(T), \nu, s_2 T})} \leq \limsup_{T \to \infty} \frac{m(B_{f, s_3 \psi(T), \nu, s_4 T})}{m(B_{f, s_1 \psi(T), \nu, s_2 T})} < \infty.
\]
Then the pair \((f, \psi)\) is uniformly acceptable.

Proof. Let \( \eta \) be an arbitrary norm on \( \mathbb{R}^n \).

(i) Let \( a = a(\psi) \in \mathbb{R}_{>1} \) and \( b = b(\psi) \in \mathbb{R}_{>0} \) be as in Definition 1.3. Let \( \nu \) be a norm on \( \mathbb{R}^n \) as in the hypotheses of (i). Fix \( k \in \mathbb{Z}_{>1} \) for which \( a^{-k} \nu \leq \eta \leq a^k \nu \). For every \( x \in \mathbb{R}^n \), we have
\[
\psi(\eta(x)) \not\preceq \psi(a^{-k} \nu(x)) \preceq b^{-k} \psi(\nu(x)).
\]
For every \( x \in \mathbb{R}^n \), we similarly have
\[
b^k \psi(\nu(x)) \preceq \psi(\eta(x)).
\]
It follows that for each \( s \in \mathbb{R}_{>0} \), we have
\[
m(A_{f, b^k \psi, \nu}) \leq m(A_{f, \psi, \eta}) \leq m(A_{f, b^{-k} \psi, \nu}).
\]
This implies the desired result.

(ii) We do not assume that \( \psi \) is regular, and we do not assume that \( \psi \) is nonincreasing. Let \( \nu \) be a norm on \( \mathbb{R}^n \) as in the hypotheses of (ii). Fix \( C \in \mathbb{R}_{>1} \) for which \( C^{-1} \nu \leq \eta \leq C \nu \). Let \( s_1, s_2, T \in \mathbb{R}_{>0} \) be arbitrary. We clearly have
\[
m(B_{f, s_1 \psi(T), \nu, C^{-1} s_2 T}) \leq m(B_{f, s_1 \psi(T), \eta, s_2 T}) \leq m(B_{f, s_1 \psi(T), \nu, C s_2 T}).
\]
The desired result now follows.

We now proceed to establish our main theorems.

Theorem 2.10. Let \( G \) be a closed subgroup of \( \text{ASL}_n(\mathbb{R}) \), let \( \Gamma \) be as in (2.1), and let \( \mathcal{P} \) be a \( \Gamma \)-invariant subset of \( \mathbb{Z}^n \). Suppose \( G \) is of \( \mathcal{P} \)-Siegel type. Let \( c = c_{\mathcal{P}} \) be as in Definition 2.1(i). Let \( f : \mathbb{R}^n \rightarrow \mathbb{R}^\ell \) be Borel measurable. Let \( \psi : \mathbb{R}_{>0} \rightarrow (\mathbb{R}_{>0})^\ell \) be regular and nonincreasing. Suppose that the pair \((f, \psi)\) is asymptotically acceptable. Let \( \eta \) and \( \nu \) be arbitrary norms on \( \mathbb{R}^n \).

(i) Suppose \( m(A_{f, \psi, \eta}) < \infty \). Then for almost every \( g \in G \) the function \( f \circ g \) is not \((\psi, \nu, \mathcal{P})\)-approximable.

(ii) Suppose \( m(A_{f, \psi, \eta}) = \infty \), and suppose that we are given \( r \in \mathbb{R}_{>1} \) for which \( G \) is of \((\mathcal{P}, r)\)-Rogers type. Then for almost every \( g \in G \) the function \( f \circ g \) is \((\psi, \nu, \mathcal{P})\)-approximable.

Proof. Let \( a = a(\psi) \in \mathbb{R}_{>1} \) and \( b = b(\psi) \in \mathbb{R}_{>0} \) be as in Definition 1.3. Let us denote elements of \( \text{ASL}_n(\mathbb{R}) \) by \( \langle h, z \rangle \), where \( h \in \text{SL}_n(\mathbb{R}) \) and \( z \in \mathbb{R}^n \); that is, \( \langle h, z \rangle : \mathbb{R}^n \rightarrow \mathbb{R}^n \) is the affine map given by \( x \mapsto z + h x \). For any \( h \in \text{SL}_n(\mathbb{R}) \), let \( \|h\| \) denote the operator norm of \( h \) that is given by
\[
\|h\| := \sup \{ \nu(hx) : x \in \mathbb{R}^n \text{ and } \nu(x) \leq 1 \}.
\]
We first prove (i). Suppose \( m(A_{f,\psi,\eta}) < \infty \). In view of (2.3), it follows that for every \( M \in \mathbb{Z}_{\geq 1} \) we have \( m(A_{f,M\psi,\eta}) < \infty \). Theorem 2.2(i) then implies that for every \( M \in \mathbb{Z}_{\geq 1} \) we have
\[
\mu_X \left( \left\{ A \in X : \# (A \cap A_{f,M\psi,\eta}) = \infty \right\} \right) = 0.
\]

Hence, the set
\[
S_1 := \bigcup_{M \in \mathbb{Z}_{\geq 1}} \{ g \in G : \# (gP \cap A_{f,M\psi,\eta}) = \infty \}
\]
satisfies \( \mu_G(S_1) = 0 \). Now let \( g = (h,z) \) be any element of \( G \) for which
\[
(2.6) \quad f \circ g \text{ is } (\psi,\nu,P)\text{-approximable.}
\]

Let \( D := \max \{ \|h\|, \|h^{-1}\| \} \), and let \( E := \nu(z) \). Let \( k \) be an element of \( \mathbb{Z}_{\geq 1} \) for which \( d^k > D \). Since \( \psi \) is regular and nonincreasing, it follows from Lemma 2.3 that there exists \( F \in \mathbb{R}_{>0} \) for which the following is true: for each \( x \in [0,E] \) and each \( y \in (E,\infty) \), we have \( \psi(y-x) \ll F \psi(y) \). Let \( N \) be any element of \( \mathbb{Z}_{\geq 1} \) with \( N > b^{-k}F \). A simple argument then yields the inclusion
\[
(2.7)\quad g \left( \left\{ x \in A_{f,g,\psi,\nu} : \nu(x) > 2DE \right\} \right) \subseteq A_{f,N\psi,\nu}.
\]

In light of (2.6) and (2.7), it follows that \( \# (gP \cap A_{f,N\psi,\nu}) = \infty \). We conclude that \( g \) belongs to the \( \mu_G \)-null set \( S_1 \). This completes the proof of (i).

The proof of (ii) proceeds along similar lines. Suppose \( m(A_{f,\psi,\eta}) = \infty \), and suppose that we are given \( r \in \mathbb{R}_{>1} \) for which \( G \) is of \((P,r)\)-Rogers type. It then follows from (2.3) and Theorem 2.2(ii) that the set
\[
S_2 := \bigcup_{M \in \mathbb{Z}_{\geq 1}} \{ g \in G : \# (gP \cap A_{f,\psi/M,\nu}) < \infty \}
\]
is \( \mu_G \)-null. Now let \( g \) be any element of \( G \) for which \( f \circ g \) is not \( (\psi,\nu,P) \)-approximable. Arguing as in the proof of (i), we conclude that \( g \in S_2 \), finishing the proof of (ii).

\[\square\]

Remark 2.11. Using (2.2) and arguing as in the proof of [14, Theorem 3.4], it is possible to enhance the qualitative conclusion of Theorem 2.10(ii) in a quantitative fashion. Since we are primarily interested in qualitative results, we decided to forego quantitative arguments.

To state the next theorem, we need the following definition.

Definition 2.12.

- Let \( t_* = (t_k)_{k \in \mathbb{Z}_{\geq 1}} \) be any strictly increasing sequence of elements of \( \mathbb{R}_{>0} \) with \( \lim_{k \to \infty} t_k = \infty \). We then say that \( f \) is \( t_* \)-uniformly \((\psi,\nu,P)\)-approximable if \( B_{f,\psi(t_k),\nu,t_k} \cap P \neq \emptyset \) for each sufficiently large \( k \in \mathbb{Z}_{\geq 1} \).
- Let \( t_* = (t_k)_{k \in \mathbb{Z}_{\geq 1}} \) be any strictly increasing sequence of elements of \( \mathbb{R}_{>0} \) with \( \lim_{k \to \infty} t_k = \infty \). We say that \( t_* \) is quasi-geometric if, in addition to the preceding, the set \( \{t_{k+1}/t_k : k \in \mathbb{Z}_{\geq 1}\} \) is bounded.

Theorem 2.13. Let \( f : \mathbb{R}^n \to \mathbb{R}^n \) and \( \psi : \mathbb{R}_{>0} \to (\mathbb{R}_{>0})^\ell \) each be Borel measurable. Suppose that the pair \((f,\psi)\) is uniformly acceptable. Let \( u_* = (u_k)_{k \in \mathbb{Z}_{\geq 1}} \) be any strictly increasing sequence of elements of \( \mathbb{R}_{>1} \) with \( \lim_{k \to \infty} u_k = \infty \). Let \( G \) be a closed subgroup of \( \text{ASL}_n(\mathbb{R}) \), let \( \Gamma \) be as in (2.1), and let \( P \) be a \( \Gamma \)-invariant subset of \( \mathbb{Z}^n \). Suppose \( G \) is of \( P \)-Siegel type, and suppose that we are given \( r \in \mathbb{R}_{>1} \) for which \( G \) is of \((P,r)\)-Rogers type. Suppose that there exists some norm \( \eta \) on \( \mathbb{R}^n \) for which
\[
(2.8) \quad \inf_{N \in \mathbb{Z}_{\geq 1}} \sum_{k=N}^{\infty} m \left( B_{f,\psi(u_k),\eta,u_k} \right)^{1-r} < \infty.
\]

Let \( \nu \) be an arbitrary norm on \( \mathbb{R}^n \). The following then hold.

(i) For almost every \( g \in G \) the function \( f \circ g \) is \( u_* \)-uniformly \((\psi,\nu,P)\)-approximable.

(ii) Suppose further that \( \psi \) is regular and nonincreasing and that the sequence \( u_* \) is quasi-geometric.

Then for almost every \( g \in G \) the function \( f \circ g \) is uniformly \((\psi,\nu,P)\)-approximable.

Proof. We argue as in the proof of [14, Theorem 3.8], appealing to the uniform acceptability of the pair \((f,\psi)\) (instead of appealing to Lemma 2.4).
Remark 2.14. We begin with the following elementary observation.

**(i)** Let \( \langle h, z \rangle \subset \text{ASL}_n(\mathbb{R}) \) introduced in the proof of Theorem 2.10 and for any \( h \in \text{SL}_n(\mathbb{R}) \), let \( \|h\| \) denote the operator norm of \( h \) given by (2.5). Define \( \pi : \text{ASL}_n(\mathbb{R}) \to \text{SL}_n(\mathbb{R}) \) and \( \rho : \text{ASL}_n(\mathbb{R}) \to \mathbb{R}^n \) by \( \pi : (h, z) \mapsto h \) and \( \rho : (h, z) \mapsto z \). Notice that each of these maps is continuous. Let \( K \) be a nonempty compact subset of \( G \) with \( K = K^{-1} \), and define

\[
D_K := \sup \{ \|h\| : h \in \pi(K) \} < \infty \quad \text{and} \quad E_K := \sup \{ \|z\| : z \in \rho(K) \} < \infty.
\]

Fix \( L \in \mathbb{Z}_{\geq 1} \) such that for each \( k \in \mathbb{Z}_{\geq L} \) we have \( u_k > 2E_K \). It follows from (2.4) and (2.8) that

\[
\inf_{N \in \mathbb{Z}_{\geq 1}} \sum_{k=1}^{N} m \left( B_{f,\psi(u_k),\eta,u_k/2D_K} \right)^{1-r} < \infty.
\]

We then apply Theorem 2.2(iii) to obtain the following: For almost every \( g \in G \) there exists \( M_g \in \mathbb{Z}_{\geq L} \) such that for each \( k \in \mathbb{Z} \) with \( k \geq M_g \) there exists some \( v_{g,k} \in P \) with

\[
\nu \left( g v_{g,k} \right) \leq \frac{u_k}{2D_K} \quad \text{and} \quad \|f(g v_{g,k})\| \leq \psi(u_k).
\]

For any such \( \mu_G \)-generic \( g \) that belongs to \( K \) and any integer \( k \geq M_g \), we have \( \nu(v_{g,k}) \leq u_k \); this may be proved by appealing to the first inequality in (2.9) and arguing as in the proof of [14] Theorem 3.8(i)]. We thus conclude that for \( \mu_G \)-almost every \( g \in K \) the function \( f \circ g \) is \( u_* \)-uniformly \((\psi, \nu, P)\)-approximable. Since \( G \) is \( \sigma \)-compact, the desired result follows.

**(ii)** Let \( a = a(\psi) \in \mathbb{R}_{>1} \) and \( b = b(\psi) \in \mathbb{R}_{>0} \) be as in Definition 1.3. Fix \( j \in \mathbb{Z}_{\geq 1} \) for which \( \sup \{ u_{k+1} / u_k : k \in \mathbb{Z}_{\geq 1} \} < a^j \). (This is possible because \( u_* \) is quasi-geometric.) Appealing once again to (2.4) and (2.8), we infer

\[
\inf_{N \in \mathbb{Z}_{\geq 1}} \sum_{k=1}^{N} m \left( B_{f, b^j \psi(u_k), \eta, u_k} \right)^{1-r} < \infty.
\]

Statement (i) of this theorem implies that for almost every \( g \in G \) the function \( f \circ g \) is \( u_* \)-uniformly \((b^j \psi, \nu, P)\)-approximable. Now let \( h : \mathbb{R}^n \to \mathbb{R}^\ell \) be any function that is \( u_\ast \)-uniformly \((b^j \psi, \nu, P)\)-approximable. Fix \( M \in \mathbb{Z}_{\geq 1} \) such that for each \( k \in \mathbb{Z}_{\geq M} \) the set \( B_{h, b^j \psi(u_k), \eta, u_k} \cap P \) is nonempty. Let \( T \in \{ u_{M+2}, +\infty \} \) be arbitrary. Then there exists \( t \in \mathbb{Z}_{M+2} \) for which \( u_t \leq T \leq u_{t+1} \). Note that there exists \( v \in P \) with \( \nu(v) \leq u_t \) and \( |b(v)| \leq b^j \psi(u_t) \). We then have \( \nu(v) \leq u_t \leq T \) and

\[
|h(v)| \leq b^j \psi(u_t) \leq b^{j-1} \psi(a^j u_t) = \psi(a^j u_t) \leq \psi(u_{t+1}) \leq \psi(T).
\]

This completes the proof.

\[\square\]

**Remark 2.14.** The infimum in (2.8) is included because \( \sum_{k=1}^{\infty} m \left( B_{f, \psi(u_k), \eta, u_k} \right)^{1-r} \) may diverge for the trivial reason that there exist finitely many \( k \in \mathbb{Z}_{\geq 1} \) for which \( m \left( B_{f, \psi(u_k), \eta, u_k} \right) = 0 \).

### 3. Applications of General Results

We begin with the following elementary observation.

**Lemma 3.1.** Let \((M, g, M)\) be an oriented \( \mathcal{C}^1 \) Riemannian manifold that is Hausdorff, second-countable, and without boundary. Let \( \sigma \) denote the Borel measure on \( M \) induced by the natural Riemannian volume form on \( M \). Let \( h : M \to \mathbb{R}^\ell \) be a \( \mathcal{C}^1 \) map, and suppose that \( h^{-1}(0_{\mathbb{R}^\ell}) \neq \emptyset \). Let \( z \in h^{-1}(0_{\mathbb{R}^\ell}) \), and suppose that \( z \) is a regular point of \( h \). Then there exist \( C = C_z \in \mathbb{R}_{>1} \), an open subset \( V = V_z \in \mathbb{R}^\ell \) with \( 0_{\mathbb{R}^\ell} \subset V \), and an open subset \( W = W_z \in M \) with \( z \in W \) such that for any Borel subset \( E \in \mathbb{R}^\ell \) with \( E \subset V \), we have

\[
C^{-1} m(E) \leq \sigma(W \cap h^{-1}(E)) \leq C m(E).
\]

In particular, \( m|_V \) and the restriction to \( V \) of the pushforward of \( \sigma|_W \) by \( h|_W \) are equivalent Borel measures.

**Proof.** For the sake of clarity, we note that \( m \) denotes Lebesgue measure on \( \mathbb{R}^\ell \). Set \( k := \dim M \). Note that \( k \geq \ell \). By the Constant Rank Theorem [14] Theorem 7.1] there exist \( \varepsilon \in \mathbb{R}_{>0} \) and maps \( \phi : (-\varepsilon, \varepsilon)^k \to M \) and \( \Phi : \mathbb{R}^\ell \to \mathbb{R}^\ell \) such that:

- the set \( \phi((-\varepsilon, \varepsilon)^k) \) is an open subset of \( M \), and \( \phi \) is a \( \mathcal{C}^1 \) diffeomorphism onto \( \phi((-\varepsilon, \varepsilon)^k) \);
- the set \( \Phi(\mathbb{R}^\ell) \) is an open subset of \( \mathbb{R}^\ell \), and \( \Phi \) is a \( \mathcal{C}^1 \) diffeomorphism onto \( \Phi(\mathbb{R}^\ell) \);
- \( \phi(0_{\mathbb{R}^k}) = z \); and
- \( \Phi \circ h \circ \phi = \pi_{\ell}((-\varepsilon, \varepsilon)^k) \), where \( \pi_{\ell} : \mathbb{R}^k \to \mathbb{R}^\ell \) is given by \((x_1, \ldots, x_k) \mapsto (x_1, \ldots, x_\ell)\).
Set $W = W_z := \phi \left( \left( -\frac{\varepsilon}{2}, \frac{\varepsilon}{2} \right)^k \right) \subseteq M$. Then $W$ is an open subset of $M$ for which

$$z \in W \subseteq \overline{W} = \phi \left( \left[ -\frac{\varepsilon}{2}, \frac{\varepsilon}{2} \right]^k \right) \supseteq \phi \left( (-\varepsilon, \varepsilon)^k \right) \subseteq M.$$ 

Note that $\Phi(0_{\mathcal{B}^1}) = 0_{\mathcal{B}^1}$. Set $V = V_z := \Phi^{-1} \left( \left( -\frac{\varepsilon}{2}, \frac{\varepsilon}{2} \right)^k \right) \subseteq \mathbb{R}^k$. Then $V$ is an open subset of $\mathbb{R}^k$ for which

$$0_{\mathcal{B}^1} \in V \subseteq \overline{V} = \Phi^{-1} \left( \left[ -\frac{\varepsilon}{2}, \frac{\varepsilon}{2} \right]^k \right) \supseteq \Phi^{-1} \left( (-\varepsilon, \varepsilon)^k \right) \subseteq \mathbb{R}^k.$$

Let $E$ be an arbitrary Borel subset of $\mathbb{R}^k$ with $E \subseteq V$. Then

$$W \cap h^{-1}(E) = \phi \left( \left( -\frac{\varepsilon}{2}, \frac{\varepsilon}{2} \right)^k \cap \pi^{-1}_k(\Phi(E)) \right).$$

Since each of $\overline{V}$ and $\overline{W}$ is compact, each of $h$ and $\pi_k$ is of class $\mathcal{C}^1$, and each of $\phi$ and $\Phi$ is a $\mathcal{C}^1$ diffeomorphism from its domain onto its image, it follows that

$$\sigma(W \cap h^{-1}(E)) \preceq_{g_M, z} m \left( \left( -\frac{\varepsilon}{2}, \frac{\varepsilon}{2} \right)^k \cap \pi^{-1}_k(\Phi(E)) \right) = \varepsilon^{k-\ell} m(\Phi(E)) \preceq_{z} m(E).$$

Let us now use the preceding lemma to derive a global statement.

**Theorem 3.2.** Let $(M, g_M)$ be an oriented $\mathcal{C}^1$ Riemannian manifold that is compact, Hausdorff, second-countable, and without boundary. Let $\sigma$ denote the Borel measure on $M$ induced by the natural Riemannian volume form on $M$. Let $h : M \to \mathbb{R}^\ell$ be a $\mathcal{C}^1$ map; suppose that $h^{-1}(0_{\mathcal{B}^1}) \neq \emptyset$ and that every element of $h^{-1}(0_{\mathcal{B}^1})$ is a regular point of $h$. Then there exists an open subset $V$ of $\mathbb{R}^k$ with $0_{\mathcal{B}^1} \in V$ such that for any Borel subset $E$ of $\mathbb{R}^k$ with $E \subseteq V$, we have

$$\sigma(h^{-1}(E)) \preceq_{M, g_M, h} m(E).$$

**Proof.** Set $Z := h^{-1}(0_{\mathcal{B}^1}) \neq \emptyset$. For every $z \in Z$, let $C_z \subset \mathbb{R}_{>1}$, $V_z \subseteq \mathbb{R}^k$ with $0_{\mathcal{B}^1} \in V_z$, and $W_z \subseteq M$ with $z \in W_z$ be as in Lemma 3.1. Since $Z$ is compact, there exist finitely many $z_1, \ldots, z_N \in Z$ such that $Z \subseteq W := \bigcup_{i=1}^N W_{z_i}$. Set $U := \bigcap_{i=1}^N V_{z_i}$ and $C := \sum_{i=1}^N C_{z_i}$. Let $V$ be an open subset of $\mathbb{R}^k$ such that $0_{\mathcal{B}^1} \in V \subseteq U$ and $h^{-1}(V) \subseteq W$. (We defer the proof of the existence of $V$ until the end of this theorem’s proof.) If $E$ is any Borel subset of $\mathbb{R}^k$ with $E \subseteq V$, then

$$C^{-1} m(E) \leq \min \{ \sigma(W_{z_i} \cap h^{-1}(E)) : 1 \leq i \leq N \} \leq \sigma(h^{-1}(E)) \leq \sum_{i=1}^N \sigma(W_{z_i} \cap h^{-1}(E)) \leq C m(E).$$

We now prove the existence of such a set $V$; suppose by way of contradiction that such a set did not exist. This would imply that for every open subset $U'$ of $\mathbb{R}^k$ with $0_{\mathcal{B}^1} \in U' \subseteq U$ there exists $y \in (M \setminus W)$ for which $h(y) \in U'$. Let $\| \cdot \|$ denote the Euclidean norm on $\mathbb{R}^\ell$. Then for each $r \in \mathbb{Z}_{>1}$ there exists some $x_r \in (M \setminus W)$ for which $h(x_r) \in U$ and $\|h(x_r)\| < r^{-1}$. Since $M$ is compact, the sequence $(x_r)_{r \in \mathbb{Z}_{>1}}$ has a convergent subsequence whose limit we denote by $x \in M$. Since $W$ is an open subset of $M$, we have $x \in (M \setminus W)$; this implies $x \notin Z$, so that $h(x) \neq 0_{\mathcal{B}^1}$. On the other hand, the sequence $(h(x_r))_{r \in \mathbb{Z}_{>1}}$ clearly converges to $0_{\mathcal{B}^1}$. The continuity of $h$ then implies $h(x) = 0_{\mathcal{B}^1}$. This is a contradiction. $\Box$

**Standing Assumptions.** Let us state here the conventions that will be in force throughout the remainder of this paper.

- We shall let $G$ denote a closed subgroup of $\text{ASL}_n(\mathbb{R})$ and let $\mathcal{P}$ denote a $\Gamma$-invariant subset of $\mathbb{Z}^n$, where $\Gamma$ is as in (2.1);
- we shall assume that $G$ is of $\mathcal{P}$-Siegel type and that we are given $r \in \mathbb{R}_{>1}$ for which $G$ is of $(\mathcal{P}, r)$-Rogers type;
- we shall let $\nu$ denote an arbitrary norm on $\mathbb{R}^n$.

We now state and prove Theorem 3.3, of which Theorem 1.7 is an immediate consequence.
Theorem 3.3. Let \( \psi = (\psi_1, \ldots, \psi_\ell) : \mathbb{R}_{\geq 0} \rightarrow (\mathbb{R}_{>0})^\ell \) be regular and nonincreasing. Let \( f = (f_1, \ldots, f_\ell) : \mathbb{R}^n \rightarrow \mathbb{R}^\ell \) be homogeneous of degree \( d = d(f) = (d_1, \ldots, d_\ell) \in (\mathbb{R}_{>0})^\ell \). Suppose further that \( f \) is continuously differentiable on \( \mathbb{R}^n_{\neq 0} \), that \( \mathcal{Z}(f) \neq \emptyset \), and that each element of \( \mathcal{Z}(f) \) is a regular point of \( f \). Let \( \xi \in \mathbb{R}^\ell \). Set \( d := \sum_{j=1}^\ell d_j \). Then the following hold.

(i) If \( \int_1^\infty t
^{\ell-1} \left( \prod_{j=1}^\ell \psi_j(t) \right) dt \) is finite (respectively, infinite), then \((\xi f) \circ g \) is \((\psi, \nu, \mathcal{P})\)-approximable for Haar-almost no (respectively, almost every) \( g \in G \).

(ii) Suppose that \( d < n \) and that the infinite series \( \sum_{k=1}^\infty \left[ 2^{k(n-d)} \prod_{j=1}^\ell \psi_j \left( 2^k \right) \right] \) converges. Then \((\xi f) \circ g \) is uniformly \((\psi, \nu, \mathcal{P})\)-approximable for Haar-almost every \( g \in G \).

Proof. We begin by attending to some preliminary matters.

Let \( \sigma_n \) denote the unique \( \text{SO}(n) \)-invariant Radon probability measure on \( \mathbb{S}^{n-1} \subset \mathbb{R}^n \). Let \( \| \cdot \| \) denote the Euclidean norm on \( \mathbb{R}^n \). Define \( h : \mathbb{S}^{n-1} \rightarrow \mathbb{R}^\ell \) to be the restriction of \( f \) to \( \mathbb{S}^{n-1} \). Note that \( h^{-1}(0_{\mathbb{R}^\ell}) = \mathcal{Z}(f) \cap \mathbb{S}^{n-1} \neq \emptyset \). Now let \( x \in h^{-1}(0_{\mathbb{R}^\ell}) \). For each \( j \in \{1, \ldots, \ell\} \), the homogeneity of \( f_j \) implies that \( \nabla f_j(x) \) is tangent to \( \mathbb{S}^{n-1} \). It follows that \( x \) is a regular point of \( f : \mathbb{R}^n \rightarrow \mathbb{R}^\ell \) if and only if \( x \) is a regular point of \( h : \mathbb{S}^{n-1} \rightarrow \mathbb{R}^\ell \). We thereby conclude that every element of \( h^{-1}(0_{\mathbb{R}^\ell}) \) is a regular point of \( h \). Theorem 3.2 may thus be applied to \( h : \mathbb{S}^{n-1} \rightarrow \mathbb{R}^\ell \). Let \( V \subseteq \mathbb{R}^\ell \) be an open neighborhood of \( 0_{\mathbb{R}^\ell} \) as in the conclusion of Theorem 3.2.

Let us now introduce a pair of mutually inverse bijections that we shall use in this proof:

\[
(3.1) \quad \mathbb{R}_{>0} \times \mathbb{S}^{n-1} \rightarrow \mathbb{R}^\ell_{\geq 0} \quad \text{given by} \quad (t, u) \mapsto tu
\]

and

\[
(3.2) \quad \mathbb{R}^n_{\neq 0} \rightarrow \mathbb{R}_{>0} \times \mathbb{S}^{n-1} \quad \text{given by} \quad x \mapsto \left( \|x\|, \frac{x}{\|x\|} \right).
\]

Finally, for each \( t \in \mathbb{R}_{>0} \), define

\[
g_t := \text{diag} \left( t^{-d_1}, \ldots, t^{-d_\ell} \right) \in \text{GL}_\ell(\mathbb{R}).
\]

(i) Let \( s \in \mathbb{R}_{>0} \). We shall show that the pair \((\xi f, \psi)\) is asymptotically acceptable by first showing that

\[
(3.3) \quad m \left( A_{\xi f, s\psi, \|\|} \right) < \infty \quad \text{if and only if} \quad \int_1^\infty t^{\ell-1} \left( \prod_{j=1}^\ell \psi_j(t) \right) dt < \infty.
\]

Using the bijections in (3.1) and (3.2) and the homogeneity of \( f \), it follows that for each \( t \in \mathbb{R}_{>0} \) and each \( u \in \mathbb{S}^{n-1} \) we have

\[
(3.4) \quad tu \in A_{\xi f, s\psi, \|\|} \quad \text{if and only if} \quad g_t(\xi - s\psi(t)) \preceq h(u) \preceq g_t(\xi + s\psi(t)).
\]

Using the boundedness of \( \psi \), we now fix \( M \in \mathbb{R}_{>2} \) such that for each \( t \in \mathbb{R}_{\geq M} \) we have

\[
\{ w \in \mathbb{R}^\ell : g_t(\xi - s\psi(t)) \preceq w \preceq g_t(\xi + s\psi(t)) \} \subseteq V.
\]

Theorem 3.2 then implies that for each \( t \in \mathbb{R}_{\geq M} \) we have

\[
(3.5) \quad \sigma_n \left( \{ u \in \mathbb{S}^{n-1} : g_t(\xi - s\psi(t)) \preceq h(u) \preceq g_t(\xi + s\psi(t)) \} \right) \asymp_{n,t,f} t^{-d} \left( 2s \right)^\ell \prod_{j=1}^\ell \psi_j(t).
\]
It then follows from (3.4) and (3.5) that
\[
m \left( \{ x \in A_{\xi f, s \psi, \| \cdot \|} : \| x \| \geq M \} \right) \\
\asymp_n \int_M^\infty t^{n-1} \sigma_n \left( \{ u \in \mathbb{S}^{n-1} : g_t (\xi - s \psi(t)) \leq h(u) \leq g_t (\xi + s \psi(t)) \} \right) dt \\
\asymp_{n, \ell, f} (2s)^{\ell} \int_M^\infty t^{n-(d+1)} \left( \prod_{j=1}^\ell \psi_j(t) \right) dt.
\]

Since \( \psi \) is bounded, this proves (3.3). Lemma 2.9(ii) then implies that the pair \((\xi f, \psi)\) is asymptotically acceptable. The desired result now follows from Theorem 2.10.

(ii) Let us prove that the pair \((\xi f, \psi)\) is uniformly acceptable. Let \(s_1, s_2 \in \mathbb{R}_{>0}\) be given. Arguing as in part (i), we infer that there exists \(M \in \mathbb{R}_{>2}\) such that for each \(T \in \mathbb{R}\) with \(T > M/s_2\), we have
\[
m \left( \{ x \in B_{\xi f, s_1 \psi(T), \| \cdot \|, s_2 T} : \| x \| \geq M \} \right) \\
\asymp_n \int_M^{s_2 T} t^{n-1} \sigma_n \left( \{ u \in \mathbb{S}^{n-1} : g_t (\xi - s_1 \psi(T)) \leq f(u) \leq g_t (\xi + s_1 \psi(T)) \} \right) dt \\
\asymp_{n, \ell, f} \int_M^{s_2 T} t^{n-1} t^{-d} \left( 2s_1 \right)^{\ell} \prod_{j=1}^\ell \psi_j(T) dt \\
\asymp_{\ell, s_1} \int_M^{s_2 T} t^{n-(d+1)} \left( \prod_{j=1}^\ell \psi_j(T) \right) dt \\
= \left( (s_2 T)^{n-d} - M^{n-d} \right) \left( \prod_{j=1}^\ell \psi_j(T) \right) \\
\asymp_{n, d, s_2, M} T^{n-d} \prod_{j=1}^\ell \psi_j(T).
\]

It follows that
\[
0 < \liminf_{T \to \infty} \frac{T^{n-d} \prod_{j=1}^\ell \psi_j(T)}{m \left( B_{\xi f, s_1 \psi(T), \| \cdot \|, s_2 T} \right)} \leq \limsup_{T \to \infty} \frac{T^{n-d} \prod_{j=1}^\ell \psi_j(T)}{m \left( B_{\xi f, s_1 \psi(T), \| \cdot \|, s_2 T} \right)} < \infty.
\]

Lemma 2.9(ii) now implies that the pair \((\xi f, \psi)\) is uniformly acceptable. It is clear from the preceding work that
\[
\inf_{N \in \mathbb{Z}_{\geq 1}} \sum_{k=N}^{\infty} m \left( B_{\xi f, \psi(2^k \cdot), \| \cdot \|, 2^k} \right)^{1-r} < \infty \quad \text{if and only if} \quad \sum_{k=1}^{\infty} \left( 2^{k(n-d)} \prod_{j=1}^\ell \psi_j(2^k) \right)^{1-r} < \infty.
\]

The desired result now follows from Theorem 2.13.

We shall now consider examples of \(f : \mathbb{R}^n \to \mathbb{R}\) that do not satisfy the nonsingularity hypotheses of Theorem 3.3. Since the measure estimates furnished by Theorem 3.2 are no longer available in this setting, we shall instead use some \textit{ad hoc} measure calculations that were performed in the authors’ previous paper: see [14 Corollaries 4.2 and 4.3]. In what follows, for each \(i \in \mathbb{Z}_{\geq 0}\), we write \(\log^i\) to denote the function \(\mathbb{R}_{>0} \to \mathbb{R}\) given by \(t \mapsto (\log t)^i\); in particular, \(\log^0\) denotes the constant function that is equal to 1 everywhere on \(\mathbb{R}_{>0}\). Our first example expands upon [14 Corollary 4.2]; in that corollary, we considered the function \(f : \mathbb{R}^n \to \mathbb{R}\) given by
\[
f(x) := \prod_{i=1}^n |x_i|
\]
and essentially proved the following result.
Lemma 3.4. [14 Corollary 4.2(ii)] Let \( f : \mathbb{R}^n \to \mathbb{R} \) be as in (3.6), let \( \overline{\psi} : \mathbb{R}_{\geq 0} \to \mathbb{R}_{> 0} \) be bounded and Borel measurable, and let \( \eta \) denote the maximum norm on \( \mathbb{R}^n \). Then there exists \( R = R (\overline{\psi}, n) \in \mathbb{R}_{\geq 1} \) such that for every Borel measurable function \( \psi : \mathbb{R}_{\geq 0} \to \mathbb{R}_{> 0} \) with \( \psi \leq \overline{\psi} \) on \( \mathbb{R}_{\geq 0} \) and any real numbers \( S < T \) with \( R \leq S \leq T \), we have

\[
(3.7) \quad m ( A_{f, \psi, \eta} \cap \{ x \in \mathbb{R}^n : S \leq \eta (x) \leq T \}) = 2^n n \int_S^T \psi (t) \left( \sum_{i=0}^{n-2} \frac{1}{i!} \log^i \left( \frac{t^n}{\psi (t)} \right) \right) dt.
\]

We remark that, strictly speaking, an application of [14 Corollary 4.2(ii)] would require the function \( \psi \) to be nonincreasing (see [14, Remark 4.4(iii)]) and would provide a value of \( R \) dependent on \( \psi \). That being said, an inspection of said corollary’s proof shows that only the boundedness and Borel measurability of \( \psi \) are required and not its monotonicity; this inspection furthermore shows that one may choose

\[
R = R (\overline{\psi}, n) := 1 + \left( \sup \{ \overline{\psi} (t) : t \in \mathbb{R}_{\geq 0} \} \right)^{1/n}.
\]

We now consider a generalized version of the function in (3.6), given by raising that function to an arbitrary power \( \omega \in \mathbb{R}_{> 0} \).

Theorem 3.5. Let \( \psi : \mathbb{R}_{\geq 0} \to \mathbb{R}_{> 0} \) be regular and nonincreasing. Let \( \omega \in \mathbb{R}_{> 0} \) be arbitrary. Let \( f : \mathbb{R}^n \to \mathbb{R} \) be given by \( f (x) := (\prod_{i=1}^n |x_i|)^\omega \). Let \( \xi \in \mathbb{R}_{\geq 0} \). Then the following hold.

(i) If

\[
\int_1^\infty \frac{\psi (t)^{1/\omega}}{t} \log^{n-2} (t) dt \quad \text{if } \xi = 0
\]

\[
\int_1^\infty \frac{\psi (t)}{t} \log^{n-2} (t) dt \quad \text{if } \xi > 0
\]

is finite (respectively, infinite), then \( (\xi f) \circ g \) is \((\psi, \nu, \mathcal{P})\)-approximable for Haar-almost no (respectively, almost every) \( g \in G \).

(ii) If the infinite series

\[
\sum_{k=1}^{\infty} \left[ k^{n-1} \psi (2k)^{1/\omega} \right]^{1-r} \quad \text{if } \xi = 0
\]

\[
\sum_{k=1}^{\infty} \left[ k^{n-1} \psi (2k) \right]^{1-r} \quad \text{if } \xi > 0
\]

converges, then \( (\xi f) \circ g \) is uniformly \((\psi, \nu, \mathcal{P})\)-approximable for Haar-almost every \( g \in G \).

Proof. If \( \lim_{t \to \infty} \psi (t) > 0 \), then note that we can easily construct a function \( \varphi : \mathbb{R}_{\geq 0} \to \mathbb{R}_{> 0} \) that is regular, nonincreasing, satisfies \( \lim_{t \to \infty} \varphi (t) = 0 \), and for which the following hold: when \( \psi \) is replaced by \( \varphi \) in Theorem 3.5, the integral in (i) diverges and the infinite series in (ii) converges. The conclusions of (i) and (ii) will then follow for \( \varphi \); we then infer that the conclusions of (i) and (ii) follow for \( \psi \) as well. We therefore assume without loss of generality that \( \lim_{t \to \infty} \psi (t) = 0 \). In concert with the regularity and monotonicity of \( \psi \), this implies that there exists some \( \lambda = \lambda (\psi) \in \mathbb{R}_{> 0} \) such that for every sufficiently large \( t \in \mathbb{R}_{\geq 1} \), we have

\[
(3.8) \quad 1 \leq - \log (\psi (t)) \leq \lambda \log (t).
\]

Let us first discuss the case \( \xi = 0 \), which was the subject of [14 Corollary 4.2]. Let us assume that \( \omega = 1 \), since the general case \( \xi = 0 \) reduces to this particular sub-case. Even though the integral and summatory conditions in that corollary and those in the \( \xi = 0 \) case of this theorem look different from one another, they are actually equivalent. Indeed, (3.8) implies that the integral

\[
\int_1^\infty \frac{\psi (t)}{t} \log^{n-2} \left( \frac{t^n}{\psi (t)} \right) dt
\]
Corollary 4.2(ii)] converges if and only if the integral $\int_{1}^{\infty} \frac{\psi(t)}{t} \log^{n-2}(t) \, dt$ converges. Likewise, the infinite series in Corollary 4.2(iii), converges if and only if the infinite series $\sum_{k=1}^{\infty} [k^{n-1} \psi(2^{k})]^{1-r}$ converges. The $\xi = 0$ case of this theorem then follows from the preceding work and Corollary 4.2.

Suppose now that $\xi > 0$. Let $\eta$ denote the maximum norm on $\mathbb{R}^{n}$.

(i) Let $s \in \mathbb{R}_{>0}$ be given. Define $\overline{\psi} : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ by $\overline{\psi}(t) := (\xi + s\psi)^{1/\omega}$. Let $R = R(\overline{\psi}, n)$ be as in Lemma 3.3. Fix $M \in \mathbb{R}$ for which $M > R$ and $s\psi(M) < \xi/2$. Then for each $t \in \mathbb{R}_{\geq M}$, we have $s\psi(t) < \xi/2$. Define $\psi : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ by

$$\psi(t) := \begin{cases} \overline{\psi}(t) & \text{if } t \in [0, M), \\ (\xi - s\psi(t))^{1/\omega} & \text{if } t \in [M, \infty). \end{cases}$$

Let $h : \mathbb{R}^{n} \to \mathbb{R}$ be given by $h(x) := \prod_{i=1}^{n} |x_{i}|$. Note that

$$A_{\overline{\psi}, \eta} \cap \eta^{-1}(\mathbb{R}_{\geq M}) \subseteq A_{\xi f, s\psi, \eta} \cap \eta^{-1}(\mathbb{R}_{\geq M})$$

and

$$m\left( A_{\xi f, s\psi, \eta} \cap \eta^{-1}(\mathbb{R}_{\geq M}) \right) = 0.$$ 

Now fix any real numbers $S$ and $T$ with $M \leq S \leq T$. Using Lemma 3.3 it follows that

$$m\left( A_{\overline{\psi}, \eta} \cap \{ x \in \mathbb{R}^{n} : S \leq \eta(x) \leq T \} \right) = 2^{n} n \int_{S}^{T} \frac{(\xi + s\psi(t))^{1/\omega}}{t} \left[ \sum_{i=0}^{n-2} \frac{1}{i!} \log^{i} \left( \frac{t^{i}}{(\xi + s\psi(t))^{1/\omega}} \right) \right] dt$$

and

$$m\left( A_{\overline{\psi}, \eta} \cap \{ x \in \mathbb{R}^{n} : S \leq \eta(x) \leq T \} \right) = 2^{n} n \int_{S}^{T} \frac{(\xi - s\psi(t))^{1/\omega}}{t} \left[ \sum_{i=0}^{n-2} \frac{1}{i!} \log^{i} \left( \frac{t^{i}}{(\xi - s\psi(t))^{1/\omega}} \right) \right] dt.$$ 

It is easy to see that

$$m\left( A_{\xi f, s\psi, \eta} \right) = \infty \quad \text{if and only if} \quad \int_{1}^{\infty} \frac{\psi(t)}{t} \log^{n-2}(t) \, dt = \infty.$$ 

This follows from (3.9) and (3.10), subtracting the right-hand side of (3.12) from that of (3.11), using (3.8) and the dominance of $\log^{n-2}$, and then performing two first-order Taylor approximations. Note that the integral criterion in (3.13) is independent of $s \in \mathbb{R}_{>0}$. Lemma 2.9(i) then implies that the pair $(\xi f, \psi)$ is asymptotically acceptable. The desired result now follows from the foregoing work and Theorem 2.10.

(ii) Let $s_{1}, s_{2} \in \mathbb{R}_{>0}$ be given. Set $J := 1 + \psi(0)$. Arguing as in part (i), we infer that there exists $M \in \mathbb{R}_{>2}$ such that for each $T \in \mathbb{R}$ with $T > M/s_{2}$, we have

$$m\left( \{ x \in B_{\xi f, s_{1}\psi(T), \eta, s_{2}T} : \eta(x) \geq M \} \right) \lesssim_{n, J, M, s_{1}, s_{2}} \int_{M}^{s_{2}T} \psi(T) \, t^{-1} \log^{n-2}(t) \, dt
$$

$$= \psi(T) \left[ \log^{n-1}(s_{2}T) - \log^{n-1}(M) \right]
$$

$$\lesssim_{n, M, s_{2}} \psi(T) \log^{n-1}(T).$$

It follows that

$$0 < \lim\inf_{T \to \infty} \frac{\psi(T) \log^{n-1}(T)}{m\left( B_{\xi f, s_{1}\psi(T), \eta, s_{2}T} \right)} \leq \lim\sup_{T \to \infty} \frac{\psi(T) \log^{n-1}(T)}{m\left( B_{\xi f, s_{1}\psi(T), \eta, s_{2}T} \right)} < \infty.$$
Lemma 3.8.\( \text{[14, Corollary 4.3(i)]} \) Let \( \psi : \mathbb{R} \to \mathbb{R} \) be regular and nonincreasing. Let \( f : \mathbb{R}^n \to \mathbb{R} \) be a function of the form \( f(x) := \left( \prod_{i=1}^n x_i \right)^{q_1/q_2} \), where \( q_1 \) and \( q_2 \) are arbitrary odd natural numbers.

Our next and final example expands upon \[14, Corollary 4.3\] and is of interest because of its relation to the Khintchine–Groshev Theorem.

Theorem 3.7. Let \( \psi : \mathbb{R}_{\geq 0} \to \mathbb{R}_{>0} \) be regular and nonincreasing. Let \( f \in \{1, \ldots, n-1\} \) and \( z = (z_1, \ldots, z_p) \in (\mathbb{R}_{>0})^p \) be given. Let \( f : \mathbb{R}^n \to \mathbb{R} \) be given by

\[
 f(x_1, \ldots, x_n) := \max \{|x_i| : 1 \leq i \leq p\}.
\]

Set \( z := \sum_{i=1}^p (z_i)^{-1} \). Let \( \xi \in \mathbb{R}_{\geq 0} \). Then the following hold.

(i) If

\[
\begin{align*}
  \int_1^\infty \psi(t)^r t^{n-(p+1)} \, dt & \quad \text{if } \xi = 0 \\
  \int_1^\infty \psi(t) t^{n-(p+1)} \, dt & \quad \text{if } \xi > 0
\end{align*}
\]

is finite (respectively, infinite), then \( (\xi f) \circ g \) is \((\psi, \nu, \mathcal{P})\)-approximable for Haar-almost no (respectively, almost every) \( g \in G \).

(ii) If the infinite series

\[
\begin{align*}
  \sum_{k=1}^\infty \left[ 2^{(n-p)k} \psi(2^k) \right]^{1-r} & \quad \text{if } \xi = 0 \\
  \sum_{k=1}^\infty \left[ 2^{(n-p)k} \psi(2^k) \right]^{1-r} & \quad \text{if } \xi > 0
\end{align*}
\]

converges, then \( (\xi f) \circ g \) is uniformly \((\psi, \nu, \mathcal{P})\)-approximable for Haar-almost every \( g \in G \).

The proof of this theorem makes use of the following lemma.

Lemma 3.8.\[14, Corollary 4.3(i)] \) Let \( f : \mathbb{R}^n \to \mathbb{R} \) be given by

\[
 f(x_1, \ldots, x_n) := \max \{|x_i| : 1 \leq i \leq p\}.
\]

Set \( z := \sum_{i=1}^p (z_i)^{-1} \). Let \( \psi : \mathbb{R}_{\geq 0} \to \mathbb{R}_{>0} \) be bounded and Borel measurable. Let \( \eta \) denote the maximum norm on \( \mathbb{R}^n \). Then there exists some \( R = R(\psi, z) \in \mathbb{R}_{\geq 1} \) such that for every Borel measurable function \( \psi : \mathbb{R}_{\geq 0} \to \mathbb{R}_{>0} \) with \( \psi \leq \psi \) on \( \mathbb{R}_{\geq 0} \) and any real numbers \( S \) and \( T \) with \( R \leq S \leq T \), we have

\[
m(A_{f,\psi,\eta} \cap \{x \in \mathbb{R}^n : S \leq \eta(x) \leq T\}) = 2^n (n-p) \int_S^T \psi(t)^r t^{n-(p+1)} \, dt.
\]

The relationship between Lemma 3.8 and \[14, Corollary 4.3(i)] is analogous to that between Lemma 3.4 and \[14, Corollary 4.2(i)]\], and similar remarks to those made earlier apply here. In particular, inspecting the proof of \[14, Corollary 4.3(i)]\ shows that one may choose

\[
 R = R(\psi, z) := 1 + \max_{1 \leq i \leq p} \left( \sup \{\psi(t) : t \in \mathbb{R}_{\geq 0}\} \right)^{1/z_i}
\]

in Lemma 3.8. The \( \xi = 0 \) case of Theorem 3.7 is already known: see \[14, Corollary 4.3\]. The proof of the \( \xi > 0 \) case of this theorem is similar to, and simpler than, that of the \( \xi > 0 \) case of Theorem 3.5; it is therefore omitted.
Remark 3.9. Let us mention that all the results in §1 (in particular, Theorems 1.7, 1.12 and 1.13 and Remarks 1.9 and 1.14) follow from those here in §3 and the fact that $G = \text{SL}_n(\mathbb{R})$ and $G = \text{ASL}_n(\mathbb{R})$ satisfy various forms of the Siegel-type and Rogers-type axioms; see [14, Theorems 2.5, 2.6, and 2.8] and the references therein for details.

Remark 3.10. We note here that one may easily deduce analogues of the statements made in Remark 1.10 for Theorems 3.7 and for the $\ell = 1$ case of Theorem 3.3. We also note that the $\ell = 1$ case of Theorem 3.3 applies to the functions discussed in Remark 1.10.

Remark 3.11. In light of the preceding results, we note that the discussion in Remark 1.15 applies in the current, more general, setting.

Acknowledgements. The co-author Skenderi would like to thank Jayadev Athreya and Jon Chaika for various discussions.
